

Multivariate time-space harmonic polynomials: a symbolic approach.

E. Di Nardo ^{*}; I. Oliva [†]

May 28, 2013

Abstract

By means of a symbolic method, in this paper we introduce a new family of multivariate polynomials such that multivariate Lévy processes can be dealt with as they were martingales. In the univariate case, this family of polynomials is known as time-space harmonic polynomials. Then, simple closed-form expressions of some multivariate classical families of polynomials are given. The main advantage of this symbolic representation is the plainness of the setting which reduces to few fundamental statements but also of its implementation in any symbolic software. The role played by cumulants is emphasized within the generalized Hermite polynomials. The new class of multivariate Lévy-Sheffer systems is introduced.

keywords: umbral calculus, multivariate Lévy process, multivariate time-space harmonic polynomial, cumulant

1 Introduction

In mathematical finance, a multivariate stochastic process \mathbf{X}_t in \mathbb{R}^d usually models the price process of hedging portfolios at time t . The tools employed to work with \mathbf{X}_t are either its probability distribution or its characteristic function. When the probability distribution of \mathbf{X}_t is known analytically, numerical algorithms are resorted aiming to compute the contingent claim's

price $E[\varphi(\mathbf{X}_t)]$ with φ some payoff function. When the characteristic function of \mathbf{X}_t is known analytically, fast Fourier transform or Monte Carlo methods are applied to multivariate integrals

$$E[\varphi(\mathbf{X}_t)] = \int_{\mathbb{R}^d} \hat{\varphi}(\mathbf{u}) E[\exp(i\mathbf{u}\mathbf{X}_t)] d\mathbf{u},$$

with $\hat{\varphi}$ the Fourier transform of φ . Both methodologies require implementations which can take some time due to the involved multivariate integrals.

Recently [3], a class of processes, called *polynomial processes*, has been introduced as follows: assume S the state space of \mathbf{X}_t , a closed subset of \mathbb{R}^d . Then there exists a multivariate polynomial $Q(\mathbf{x}, t)$ in

$$\text{Pol}_{\leq m}(S) = \left\{ \sum_{|\mathbf{k}|=0}^m c_{\mathbf{k}} \mathbf{x}^{\mathbf{k}} \mid \mathbf{x} \in S, c_{\mathbf{k}} \in \mathbb{R} \right\} \quad (1.1)$$

such that a martingale property holds ¹

$$E[Q(\mathbf{X}_t, t) | \mathbf{X}_s] = Q(\mathbf{X}_s, s) \quad (1.2)$$

for $s \leq t$. The name is a consequence of the main property shared by these processes. The polynomials (1.1) originated in conjunction with random matrix theory and multivariate statistics of ensembles. In [3], these processes are employed together with the reduction–variance method for the pricing and the hedging of some bounded measurable European claims. The attention is essentially focused on the properties shared by the class of stochastic processes $Q(\mathbf{X}_t, t)$, as for example affine processes or Feller processes with quadratic squared diffusion coefficients. The computation of their coefficients is not central and requires the computation of a matrix exponential². In order to characterize the polynomials Q , Haar measure and zonal polynomials are involved. A computational efficient way to deal with zonal polynomials is not yet available: in particular, as coefficients of hypergeometric functions, zonal polynomials have manageable expressions only on the unitary group. In the univariate case, this class of polynomials has been deeply analyzed by different authors, see [22] and references therein. They are called *time-space harmonic* polynomials. For Lévy processes \mathbf{X}_t , the

¹In (1.1), the multi-index notation is employed. Recall that a (d -dimensional) multi-index \mathbf{k} is a d -tuple $\mathbf{k} = (k_1, \dots, k_d)$ of nonnegative integers, such that $|\mathbf{k}| = k_1 + \dots + k_d$, $\mathbf{k}! = k_1! \dots k_d!$. We set $\mathbf{x}^{\mathbf{k}} = x_1^{k_1} x_2^{k_2} \dots x_d^{k_d}$, $c_{\mathbf{k}} = c_{k_1, k_2, \dots, k_d}$.

²If X is a real or complex $n \times n$ matrix, then the *matrix exponential* of X is a $n \times n$ matrix e^X whose power series is $e^X = \sum_{\mathbf{k} \geq 0} X^{\mathbf{k}} / \mathbf{k}!$.

main advantage of employing the polynomial process $Q(\mathbf{X}_t, t)$ is the martingale property (1.2), fundamental in the martingale pricing [17], which not necessarily holds for Lévy processes.

The multivariate Faà di Bruno formula is the main tool proposed in this paper in order to characterize multivariate time-space harmonic polynomials. In the univariate case, this formula gives the m -th derivative of a composite function, that is, if f and g are functions with a sufficient number of derivatives, then

$$\frac{g^{(m)}[f(t)]}{m!} = \sum \frac{g^{(k)}[f(t)]}{b_1!b_2!\dots b_m!} \left(\frac{f^{(1)}(t)}{1!}\right)^{b_1} \left(\frac{f^{(2)}(t)}{2!}\right)^{b_2} \dots \left(\frac{f^{(m)}(t)}{m!}\right)^{b_m},$$

where the sum is over all m -tuples of nonnegative integers (b_1, \dots, b_m) such that $b_1 + 2b_2 + \dots + mb_m = m$ and $k = b_1 + \dots + b_m$. This formula can be extended to the multivariate case by using multi-index partitions, see [6]. Its implementation is quite cumbersome, but recently an optimized algorithm has been introduced [6] by using a symbolic method, known in the literature as the classical umbral calculus [18]. Its main device is to represent number sequences by suitable symbols via a linear functional, resembling the expectation of random variables (r.v.'s). Within this symbolic method, the multivariate Faà di Bruno formula is computed by using suitable multivariate polynomials whose indeterminates are replaced by different polynomials. In this paper we characterize a bases for the space of multivariate time-space harmonic polynomials (1.1) involving Lévy processes. These polynomials have a simple expression, easily implementable in any symbolic software by using the algorithms addressed in [6].

Special families of multivariate polynomials such as the Hermite polynomials, the Bernoulli polynomials and the Euler polynomials are then recovered. The new class of multivariate Lévy-Sheffer systems is introduced. The remainder of the paper is organized in order to resume terminology, notations and some basic definitions of the symbolic method. For the symbolic univariate Lévy process introduced in [10], we add two more examples: the stable and the inverse Gaussian process.

Since orthogonal polynomials are currently employed in mathematical finance [20], an interesting application which deserves further deepening studies is the orthogonal property of multivariate time-space harmonic polynomials. Some preliminary results are given in [13]. These are certainly connected to multivariate Sheffer sequences [1] whose treatment would indeed benefit of an umbral approach. Finally, since the symbolic method has already been applied within random matrix theory [7] in studying their

cumulants, we believe fruitful to employ this setting early to matrix-valued polynomial processes.

2 The symbolic method

The symbolic method we refer is a syntax consisting of a set $\mathcal{A} = \{\alpha, \beta, \gamma, \dots\}$ of symbols called *umbrae* and a linear functional $E : \mathbb{R}[x][\mathcal{A}] \rightarrow \mathbb{R}[x]$, with \mathbb{R} the set of real numbers, called *evaluation*, such that $E[1] = 1$ and

$$E[x^n \alpha^i \beta^j \dots \gamma^k] = x^n E[\alpha^i] E[\beta^j] \dots E[\gamma^k] \quad (\text{uncorrelation property})$$

for all distinct umbrae $\alpha, \beta, \dots, \gamma \in \mathcal{A}$ and for all nonnegative integers n, i, j, \dots, k . A unital sequence of real numbers $a_0 = 1, a_1, a_2, \dots$ is said to be *umbrally represented* by an umbra α if $E[\alpha^k] = a_k$, for all $k \geq 0$. By analogy with moments of a r.v., the k -th element of the sequence $\{a_k\}$ is called the k -th moment of the umbra α .

Two distinct umbrae α and γ are said to be *similar* if and only if they represent the same sequence of moments

$$\alpha \equiv \gamma \Leftrightarrow E[\alpha^k] = E[\gamma^k], \quad \text{for } k = 0, 1, 2, \dots$$

A polynomial $p \in \mathbb{R}[\mathcal{A}]$ is called an *umbral polynomial*. The *support* of p is the set of all occurring umbrae of \mathcal{A} . Two umbral polynomials p and q are said to be *umbrally equivalent* if and only if $E[p] = E[q]$, in symbols $p \simeq q$. They are uncorrelated when their supports are disjoint.

The formal power series

$$u + \sum_{k \geq 1} \alpha^k \frac{z^k}{k!} \in \mathbb{R}[\mathcal{A}][z] \quad (2.1)$$

is the *generating function* of the umbra α and it is denoted by $e^{\alpha z}$. By extending coefficientwise the notion of umbral equivalence, any exponential formal power series

$$f(z) = 1 + \sum_{k \geq 1} a_k \frac{z^k}{k!} \quad (2.2)$$

can be umbrally represented by a formal power series (2.1). Indeed, if the sequence $\{a_k\}$ is umbrally represented by an umbra α , we have $f(z) = E[e^{\alpha z}]$. The formal power series (2.2) is denoted by $f(\alpha, z)$ to underline the role played by the moments of the umbra α . Special umbrae are

a) the *singleton umbra* χ with generating function $f(\chi, z) = 1 + z$;

- b) the *unity umbra* u with generating function $f(u, z) = e^z$;
- c) the *augmentation umbra* ε with generating function $f(\varepsilon, z) = 1$;
- d) the *Bell umbra* β with generating function $f(\beta, z) = \exp\{e^z - 1\}$.

A class of umbrae useful in the following is given by the so-called *auxiliary umbrae*. An auxiliary umbra is a symbol not in the alphabet \mathcal{A} but defined in such a way that it represents special sequences of moments. Then, the alphabet \mathcal{A} is extended by inserting these auxiliary symbols as they were elements of \mathcal{A} . For example, by the auxiliary symbol $\alpha \dot{+} \gamma$, we denote the *disjoint sum* of two umbrae, representing the sequence of coefficients of $f(\alpha, z) + f(\gamma, z) - 1$. Therefore we write $f(\alpha \dot{+} \gamma, z) = f(\alpha, z) + f(\gamma, z) - 1$ and deal with $\alpha \dot{+} \gamma$ as it was an element of the alphabet \mathcal{A} . One more example, which will be largely employed in the rest of the paper, is the *dot-product* $n.\alpha$ of a nonnegative integer n and an umbra α . Let us consider the set $\{\alpha', \alpha'', \dots, \alpha'''\}$ of n distinct umbrae, similar to the umbra α but uncorrelated each other. Define the symbol $n.\alpha$ as $n.\alpha = \alpha' + \alpha'' + \dots + \alpha'''$. Then, we have $f(n.\alpha, z) = [f(\alpha, z)]^n$. The moments of $n.\alpha$ are (see [12] for further details)

$$E[(n.\alpha)^k] = \sum_{i=1}^k (n)_i B_{k,i}(a_1, a_2, \dots, a_{k-i+1}), \quad \text{for all } k \geq 1, \quad (2.3)$$

where $B_{k,i}(a_1, a_2, \dots, a_{k-i+1})$ are the partial exponential Bell polynomials [4], $(n)_i = n(n-1) \cdots (n-i+1)$ is the lower factorial and $\{a_j\}$ are moments of α .

Equation (2.3) suggests a way to define new auxiliary umbrae depending on a real parameter t . Indeed, the k -th moment of the dot-product $n.\alpha$ is a polynomial, say $q_k(n)$, of degree k in n . The integer n can be replaced by any $t \in \mathbb{R}$ so that

$$q_k(t) = \sum_{i=1}^k (t)_i B_{k,i}(a_1, a_2, \dots, a_{k-i+1}) \quad \text{for all } k \geq 1,$$

still denotes a polynomial of degree k in t . The symbol $t.\alpha$ is then introduced as the auxiliary umbra such that $E[(t.\alpha)^k] = q_k(t)$, for all non-negative integers k . This symbol is called the dot-product of t and α . Its generating function is $f(t.\alpha, z) = [f(\alpha, z)]^t$. By using similar arguments, the real parameter t could be replaced by any umbra γ . The umbra $\gamma.\alpha$ representing $\{E[q_k(\gamma)]\}_{k \geq 0}$ is the dot-product of γ and α and $f(\gamma.\alpha, z) =$

$f(\gamma, \log[f(\alpha, z)])$. These replacements are the main device of the symbolic method. For example, we can replace the umbra γ by the auxiliary umbra $t.\beta$ such that $E[(t.\beta)_k] = t^k$ for all $k \geq 1$, see [5]. Then we have

$$q_k(t.\beta.\alpha) = \sum_{i=1}^k t^i B_{k,i}(a_1, a_2, \dots, a_{k-i+1}) \quad \text{for all } k \geq 1, \quad (2.4)$$

and $(t.\beta).\alpha \equiv t.(\beta.\alpha)$. We omit the parentheses when they are not necessary for the computations. The generating function of $t.\beta.\alpha$ is

$$f(t.\beta.\alpha, z) = \exp\{t[f(\alpha, z) - 1]\}. \quad (2.5)$$

Again, we can replace t in (2.4) with an umbra γ . The umbra $\gamma.\beta.\alpha$ is the composition umbra of γ and α , see [5].

2.1 Symbolic Lévy processes

Recall that a stochastic process $\{X_t\}_{t \geq 0}$ on \mathbb{R} is a *Lévy process* if its increments $X_t - X_{t-1}$ are independent and stationary r.v.'s. Lévy processes share the infinite divisibility property [19] and their symbolic representation generalizes this own property. Indeed the following theorem has been proved in [10].

Theorem 2.1. *Let $\{X_t\}_{t \geq 0}$ be a Lévy process with finite moments for all t and let α be an umbra such that $f(\alpha, z) = E[e^{zX_1}]$. Then for any $t \geq 0$, the moment sequence of the Lévy process $\{X_t\}_{t \geq 0}$ is umbrally represented by the family of auxiliary umbrae $\{t.\alpha\}_{t \geq 0}$.*

Theorem 2.1 states that if the moments of an umbra α are all finite, the family of auxiliary umbrae $\{t.\alpha\}_{t \geq 0}$ is the umbral counterpart of a Lévy process $\{X_t\}_{t \geq 0}$ such that $E[X_t^k] = E[(t.\alpha)^k]$, for all nonnegative integers k . In [8] and [10], several examples of symbolic Lévy processes have been given. Here we add two more examples.

The m -stable process. A m -stable process is a Lévy process whose increments are independent, stationary and m -stable distributed. In particular the m -stable process is an example of stochastic process with not convergent moment generating function in any neighborhood of zero. Nevertheless, since the symbolic method asides from the convergence of formal power series (2.2), we are able to characterize Lévy processes which are m -stables.

Definition 2.2. An umbra $\alpha \in \mathcal{A}$ is said to be *stable* with *stability parameter* $m \in [0, 2)$ if there exist $b_n, c_n \in \mathbb{R}$ such that $n.\alpha \equiv c_n\alpha + b_n.u$, where u is the unity umbra.

Previous definition parallels the same given in probability theory [14, 15] for stable r.v.'s and, by using similar arguments, one can prove that $c_n = n^{1/m}$ (see [15] for further details). From Definition 2.2, we have

$$b_n.u \equiv n.\alpha + n^{1/m}(-1.\alpha)$$

where $-1.\alpha$ is the inverse of the umbra α , that is the auxiliary umbra such that $\alpha + (-1.\alpha) \equiv \varepsilon$.

Definition 2.3. The family of auxiliary umbrae $\{t.\alpha\}_{t \geq 0}$, where α is a stable umbra, is a symbolic stable Lévy process.

Inverse Gaussian process. An inverse Gaussian process $\{X_t^{(IG)}\}_{t \geq 0}$ is a Lévy process with independent, stationary and inverse Gaussian distributed increments [2], that is $X_t^{(IG)} \sim IG(a, b)$ with $a, b > 0$. The moment generating function of $X_t^{(IG)}$ is

$$E \left[e^{zX_t^{(IG)}} \right] = \exp \left\{ t \frac{b}{a} \left[1 - \left(\sqrt{1 - \frac{2a^2z}{b}} \right) \right] \right\}. \quad (2.6)$$

To obtain the symbolic expression of an inverse Gaussian process, we need to recall the notion of compositional inverse of an umbra. Indeed, if α is an umbra with generating function $f(\alpha, z)$, then the compositional inverse of α is the umbra $\alpha^{<-1>}$ such that $\alpha.\beta.\alpha^{<-1>} \equiv \alpha^{<-1>}.\beta.\alpha \equiv \chi$. In particular its generating function is such that $f(\alpha^{<-1>}, z) = f^{<-1>}(\alpha, z)$ where

$$f[\alpha, f^{<-1>}(\alpha, z) - 1] = f^{<-1>}[\alpha, f(\alpha, z) - 1] = 1 + z. \quad (2.7)$$

Definition 2.4. An umbra α is said to be an *inverse Gaussian umbra* if $-\alpha \equiv \beta.(-b\chi + \sqrt{a}\delta)^{<-1>}$ with χ the singleton umbra and δ the Gaussian umbra, that is an umbra with generating function $f(\delta, z) = 1 + z^2/2$.

Set $\sqrt{a} = s$. Definition 2.4 moves from the generating function given in (2.6). Indeed we have

$$f(-\alpha, z) = f[\beta.(-b\chi + s\delta)^{<-1>}, z] = \exp\{f[(-b\chi + s\delta)^{<-1>}, z] - 1\}.$$

For the sake of simplicity, set $f^{<-1>}(-b\chi + s\delta, z) = \bar{f}(z)$, so from (2.7) we have $f(-b\chi + s\delta, \bar{f}(z) - 1) = 1 + z$. Since $f(-b\chi + s\delta, z) = (1 - bz) + s^2z^2/2$

then $s^2 \bar{f}^2(z) - 2(b + s^2)\bar{f}(z) + 2b + s^2 - 2z = 0$. Solving the previous equation with respect to $\bar{f}(z)$ and replacing $s^2 = a$ we obtain

$$\bar{f}(z) = 1 + \frac{b}{a} \left[1 \pm \sqrt{1 + \frac{2za}{b^2}} \right]. \quad (2.8)$$

As $\bar{f}(0) = 1$, see (2.2), in (2.8) we choose the minus sign so that

$$f[\beta.(-b\chi + s\delta)^{\langle -1 \rangle}, z] = \exp \left\{ \frac{b}{a} \left[1 - \sqrt{1 + \frac{2za}{b^2}} \right] \right\}.$$

By using (2.5), we recover the generating function (2.6).

Definition 2.5. The family of auxiliary umbrae $\{t.\beta.(-b\chi + \sqrt{a}\delta)^{\langle -1 \rangle}\}_{t \geq 0}$ is the symbolic inverse Gaussian process.

3 Multivariate time-space harmonic polynomials

In the univariate classical umbral calculus, the main device is to replace a_n with α^n via the linear evaluation E . In the same way, the main device of the multivariate case is to replace sequences like $\{g_{i_1, i_2, \dots, i_d}\}$ with a product of powers $\mu_1^{i_1} \mu_2^{i_2} \dots \mu_d^{i_d}$, where $\{\mu_1, \mu_2, \dots, \mu_d\}$ are umbral monomials and i_1, \dots, i_d are nonnegative integers. Note that the supports of the umbral monomials in $\{\mu_1, \mu_2, \dots, \mu_d\}$ are not necessarily disjoint. A multivariate version of this symbolic method has been given first in [6].

In order to manage products like $\mu_1^{i_1} \mu_2^{i_2} \dots \mu_d^{i_d}$ as powers of an umbra, we will use the multi-index notation. A sequence $\{g_{\mathbf{v}}\}_{\mathbf{v} \in \mathbb{N}_0^d}$ with $g_{\mathbf{v}} = g_{v_1, \dots, v_d}$ and $g_{\mathbf{0}} = 1$ is umbrally represented by the d -tuple $\boldsymbol{\mu}$ if $E[\boldsymbol{\mu}^{\mathbf{v}}] = g_{\mathbf{v}}$, for all $\mathbf{v} \in \mathbb{N}_0^d$. Then $g_{\mathbf{v}}$ is called the *multivariate moment* of $\boldsymbol{\mu}$.

Two d -tuples $\boldsymbol{\mu}$ and $\boldsymbol{\nu}$ of umbral monomials are said to be similar if they represent the same sequence of multivariate moments, in symbols $E[\boldsymbol{\mu}^{\mathbf{v}}] = E[\boldsymbol{\nu}^{\mathbf{v}}]$, for all $\mathbf{v} \in \mathbb{N}_0^d$. Two d -tuples $\boldsymbol{\mu}$ and $\boldsymbol{\nu}$ of umbral monomials are said to be uncorrelated if $E[\boldsymbol{\mu}^{\mathbf{v}_1} \boldsymbol{\nu}^{\mathbf{v}_2}] = E[\boldsymbol{\mu}^{\mathbf{v}_1}] E[\boldsymbol{\nu}^{\mathbf{v}_2}]$, for all $\mathbf{v}_1, \mathbf{v}_2 \in \mathbb{N}_0^d$.

The exponential multivariate formal power series

$$e^{\boldsymbol{\mu} \mathbf{z}^T} = \mathbf{u} + \sum_{k \geq 1} \sum_{\substack{\mathbf{v} \in \mathbb{N}_0^d \\ |\mathbf{v}|=k}} \boldsymbol{\mu}^{\mathbf{v}} \frac{\mathbf{z}^{\mathbf{v}}}{\mathbf{v}!} \quad (3.1)$$

is said to be the *generating function* of the d -tuple $\boldsymbol{\mu}$. Now, assume $\{g_{\mathbf{v}}\}_{\mathbf{v} \in \mathbb{N}_0^d}$ umbrally represented by the d -tuple $\boldsymbol{\mu}$. If the sequence $\{g_{\mathbf{v}}\}_{\mathbf{v} \in \mathbb{N}_0^d}$ has exponential multivariate generating function

$$f(\boldsymbol{\mu}, \mathbf{z}) = 1 + \sum_{k \geq 1} \sum_{\substack{\mathbf{v} \in \mathbb{N}_0^d \\ |\mathbf{v}|=k}} g_{\mathbf{v}} \frac{\mathbf{z}^{\mathbf{v}}}{\mathbf{v}!},$$

suitably extending coefficientwise the action of E to the generating function (3.1), we have $E[e^{\boldsymbol{\mu}\mathbf{z}^T}] = f(\boldsymbol{\mu}, \mathbf{z})$. Henceforth, when no confusion occurs, we refer to $f(\boldsymbol{\mu}, \mathbf{z})$ as the generating function of the d -tuple $\boldsymbol{\mu}$.

As done in the univariate case, we can introduce the auxiliary umbra $n.\boldsymbol{\mu}$. To express its moments, the notion of multi-index partition [6] needs to be recalled.

Definition 3.1. A partition $\boldsymbol{\lambda}$ of a multi-index \mathbf{v} , in symbols $\boldsymbol{\lambda} \vdash \mathbf{v}$, is a matrix $\boldsymbol{\lambda} = (\lambda_{ij})$ of nonnegative integers and with no zero columns in lexicographic order \prec such that $\lambda_{r_1} + \lambda_{r_2} + \dots + \lambda_{r_k} = v_r$ for $r = 1, 2, \dots, d$.

The number of columns of $\boldsymbol{\lambda}$ is denoted by $l(\boldsymbol{\lambda})$. The notation $\boldsymbol{\lambda} = (\boldsymbol{\lambda}_1^{r_1}, \boldsymbol{\lambda}_2^{r_2}, \dots)$ represents the matrix $\boldsymbol{\lambda}$ with r_1 columns equal to $\boldsymbol{\lambda}_1$, r_2 columns equal to $\boldsymbol{\lambda}_2$ and so on, where $\boldsymbol{\lambda}_1 \prec \boldsymbol{\lambda}_2 \prec \dots$. We set $\mathbf{m}(\boldsymbol{\lambda}) = (r_1, r_2, \dots)$, $\mathbf{m}(\boldsymbol{\lambda})! = r_1!r_2!\dots$ and $\boldsymbol{\lambda}! = \boldsymbol{\lambda}_1!\boldsymbol{\lambda}_2!\dots$. Then, for a nonnegative integer n we have

$$(n.\boldsymbol{\mu})^{\mathbf{v}} \simeq \sum_{\boldsymbol{\lambda} \vdash \mathbf{v}} \frac{\mathbf{v}!}{\mathbf{m}(\boldsymbol{\lambda})\boldsymbol{\lambda}!} (n)_{l(\boldsymbol{\lambda})} \boldsymbol{\mu}_{\boldsymbol{\lambda}}, \quad (3.2)$$

where $\boldsymbol{\mu}_{\boldsymbol{\lambda}} = (\boldsymbol{\mu}'^{\lambda_1})^{r_1} (\boldsymbol{\mu}''^{\lambda_2})^{r_2} \dots$, with $\boldsymbol{\mu}', \boldsymbol{\mu}'', \dots$ uncorrelated d -tuple similar to $\boldsymbol{\mu}$. By replacing n with the real parameter t , we have

$$(t.\boldsymbol{\mu})^{\mathbf{v}} \simeq \sum_{\boldsymbol{\lambda} \vdash \mathbf{v}} \frac{\mathbf{v}!}{\mathbf{m}(\boldsymbol{\lambda})\boldsymbol{\lambda}!} (t)_{l(\boldsymbol{\lambda})} \boldsymbol{\mu}_{\boldsymbol{\lambda}}, \quad (3.3)$$

while by replacing n with the auxiliary umbra $t.\beta$ we obtain

$$(t.\beta.\boldsymbol{\mu})^{\mathbf{v}} \simeq \sum_{\boldsymbol{\lambda} \vdash \mathbf{v}} \frac{\mathbf{v}!}{\mathbf{m}(\boldsymbol{\lambda})\boldsymbol{\lambda}!} t^{l(\boldsymbol{\lambda})} \boldsymbol{\mu}_{\boldsymbol{\lambda}}. \quad (3.4)$$

The auxiliary umbrae $t.\boldsymbol{\mu}$ and $t.\beta.\boldsymbol{\mu}$ are the building blocks in dealing with symbolic Lévy processes and multivariate time-space harmonic polynomials. For their definition, the conditional evaluation with respect to an umbral d -tuple $\boldsymbol{\mu}$ needs to be introduced.

Definition 3.2. Assume $\mathcal{X} = \{\mu_1, \mu_2, \dots, \mu_d\}$. The linear operator

$$E(\cdot | \boldsymbol{\mu}) : \mathbb{R}[x_1, \dots, x_d][\mathcal{A}] \longrightarrow \mathbb{R}[\mathcal{X}]$$

such that $E(1 | \boldsymbol{\mu}) = 1$ and

$$E(x_1^{l_1} x_2^{l_2}, \dots, x_d^{l_d} \boldsymbol{\mu}^i \boldsymbol{\nu}^j \boldsymbol{\gamma}^k \dots | \boldsymbol{\mu}) = x_1^{l_1} x_2^{l_2} \dots x_d^{l_d} \boldsymbol{\mu}^i E[\boldsymbol{\nu}^j] E[\boldsymbol{\gamma}^k] \dots$$

for uncorrelated d -tuples $\boldsymbol{\mu}, \boldsymbol{\nu}, \boldsymbol{\gamma}, \dots$, for $\mathbf{m}, \mathbf{i}, \mathbf{j}, \dots \in \mathbb{N}_0^d$ and $\{l_i\}_{i=1}^d$ non-negative integers, is called *conditional evaluation* with respect to the umbral d -tuple $\boldsymbol{\mu}$.

Definition 3.3. Let $\{P(\mathbf{x}, t)\} \in \mathbb{R}[x_1, \dots, x_d]$ be a family of polynomials indexed by $t \geq 0$. The polynomial $P(\mathbf{x}, t)$ is said to be a *multivariate time-space harmonic polynomial* with respect to the family of auxiliary umbrae $\{t.\boldsymbol{\mu}\}_{t \geq 0}$ if and only if

$$E(P(t.\boldsymbol{\mu}, t) | s.\boldsymbol{\mu}) = P(s.\boldsymbol{\mu}, s), \quad \text{for all } s \leq t. \quad (3.5)$$

Since $f[(n+m).\boldsymbol{\mu}, \mathbf{z}] = f(\boldsymbol{\mu}, \mathbf{z})^{n+m} = f(n.\boldsymbol{\mu}, \mathbf{z}) f(m.\boldsymbol{\mu}, \mathbf{z})$, then

$$(n+m).\boldsymbol{\mu} \equiv n.\boldsymbol{\mu} + m.\boldsymbol{\mu}', \quad (3.6)$$

with $\boldsymbol{\mu}$ and $\boldsymbol{\mu}'$ uncorrelated d -tuples of umbral monomials. Then, for $E(\cdot | \boldsymbol{\mu})$ is reasonable to assume

$$E[\{(n+m).\boldsymbol{\mu}\}^{\mathbf{v}} | n.\boldsymbol{\mu}] = E[\{n.\boldsymbol{\mu} + m.\boldsymbol{\mu}'\}^{\mathbf{v}} | n.\boldsymbol{\mu}], \quad (3.7)$$

for all nonnegative integers n, m and for all $\mathbf{v} \in \mathbb{N}_0^d$. If $n \neq m$, then equation (3.7) could be rewritten as

$$E[\{(n+m).\boldsymbol{\mu}\}^{\mathbf{v}} | n.\boldsymbol{\mu}] = E[\{n.\boldsymbol{\mu} + m.\boldsymbol{\mu}\}^{\mathbf{v}} | n.\boldsymbol{\mu}], \quad (3.8)$$

since $n.\boldsymbol{\mu}$ and $m.\boldsymbol{\mu}$ are uncorrelated auxiliary umbrae. We will use (3.8) when no misunderstanding occurs. Thanks to equation (3.7) we have

$$\begin{aligned} E[\{(n+m).\boldsymbol{\mu}\}^{\mathbf{v}} | n.\boldsymbol{\mu}] &= E \left[\sum_{\mathbf{k} \leq \mathbf{v}} \binom{\mathbf{v}}{\mathbf{k}} (n.\boldsymbol{\mu})^{\mathbf{k}} (m.\boldsymbol{\mu})^{\mathbf{v}-\mathbf{k}} \middle| n.\boldsymbol{\mu} \right] \\ &= \sum_{\mathbf{k} \leq \mathbf{v}} \binom{\mathbf{v}}{\mathbf{k}} (n.\boldsymbol{\mu})^{\mathbf{k}} E[(m.\boldsymbol{\mu})^{\mathbf{v}-\mathbf{k}}], \end{aligned} \quad (3.9)$$

where $\mathbf{k} \leq \mathbf{v} \Leftrightarrow k_i \leq v_i$, for all $i = 1, \dots, d$ and $\binom{\mathbf{k}}{\mathbf{v}} = \binom{k_1}{v_1} \cdots \binom{k_d}{v_d}$. By analogy with (3.8) and (3.9), we have $(t+s).\boldsymbol{\mu} \equiv t.\boldsymbol{\mu} + s.\boldsymbol{\mu}$ and for $t \geq 0$

$$E[(t.\boldsymbol{\mu})^{\mathbf{v}} | s.\boldsymbol{\mu}] = \sum_{\mathbf{k} \leq \mathbf{v}} \binom{\mathbf{v}}{\mathbf{k}} (s.\boldsymbol{\mu})^{\mathbf{k}} E[\{(t-s).\boldsymbol{\mu}\}^{\mathbf{v}-\mathbf{k}}]. \quad (3.10)$$

As $s, t \in \mathbb{R}$, recall that the auxiliary umbra $-t.\boldsymbol{\mu}$ denotes the inverse of $t.\boldsymbol{\mu}$ that is $-t.\boldsymbol{\mu} + t.\boldsymbol{\mu} \equiv \boldsymbol{\varepsilon}$ where $\boldsymbol{\varepsilon}$ is the d -tuple such that $\boldsymbol{\varepsilon} = (\varepsilon_1, \varepsilon_2, \dots, \varepsilon_d)$, with $\{\varepsilon_i\}$ uncorrelated augmentation umbrae.

Theorem 3.6 allows us to introduce the class of multivariate time-space harmonic polynomials with respect to a symbolic d -dimensional Lévy process. Symbolic d -dimensional Lévy processes have been introduced in [9]. Here we recall the main results.

Definition 3.4. A stochastic process $\{\mathbf{X}_t\}_{t \geq 0}$ on \mathbb{R}^d is a *multidimensional Lévy process* if

- (i) $\mathbf{X}_0 = \mathbf{0}$ a.s.
- (ii) For all $n \geq 1$ and for all $0 \leq t_1 \leq t_2 \leq \dots \leq t_n < \infty$, the r.v.'s $\mathbf{X}_{t_2} - \mathbf{X}_{t_1}, \mathbf{X}_{t_3} - \mathbf{X}_{t_2}, \dots$ are independent.
- (iii) For all $s \leq t$, $\mathbf{X}_{t+s} - \mathbf{X}_s \stackrel{d}{=} \mathbf{X}_t$.
- (iv) For all $\varepsilon > 0$, $\lim_{h \rightarrow 0} P(|\mathbf{X}_{t+h} - \mathbf{X}_t| > \varepsilon) = 0$.
- (v) $t \mapsto \mathbf{X}_t(\omega)$ are càdlàg, for all $\omega \in \Omega$, with Ω the underlying sample space.

The moment generating function of a *multidimensional Lévy process* is such that $\varphi_{\mathbf{X}_1}(\mathbf{z}) = E[e^{\mathbf{z} \cdot \mathbf{X}_1^T}]$, with $\mathbf{z} \in \mathbb{R}^d$. If we denote by $\boldsymbol{\mu}$ the d -tuple such that $f(\boldsymbol{\mu}, \mathbf{z}) = \varphi_{\mathbf{X}_1}(\mathbf{z})$, then symbolic multidimensional Lévy processes can be constructed as done in the previous section.

Theorem 3.5. A Lévy process $\{\mathbf{X}_t\}_{t \geq 0}$ in \mathbb{R}^d is umbrally represented by $\{t.\boldsymbol{\mu}\}_{t \geq 0}$, where $\boldsymbol{\mu}$ is such that $g_{\mathbf{v}} = E[\boldsymbol{\mu}^{\mathbf{v}}] = E[\mathbf{X}_1^{\mathbf{v}}]$, for all $\mathbf{v} \in \mathbb{N}_0^d$.

Theorem 3.6. For all $\mathbf{v} \in \mathbb{N}_0^d$, the family of polynomials

$$Q_{\mathbf{v}}(\mathbf{x}, t) = E[(\mathbf{x} - t.\boldsymbol{\mu})^{\mathbf{v}}] \in \mathbb{R}[x_1, \dots, x_d] \quad (3.11)$$

is time-space harmonic with respect to $\{t.\boldsymbol{\mu}\}_{t \geq 0}$.

Proof. We need to prove that the family of polynomials $Q_v(\mathbf{x}, t)$ satisfies equality (3.5). Observe that

$$Q_v(\mathbf{x}, t) = E \left[\sum_{\mathbf{k} \leq \mathbf{v}} \binom{\mathbf{v}}{\mathbf{k}} \mathbf{x}^{v-k} (-t \cdot \boldsymbol{\mu})^k \right] = \sum_{\mathbf{k} \leq \mathbf{v}} \binom{\mathbf{v}}{\mathbf{k}} \mathbf{x}^{v-k} E[(-t \cdot \boldsymbol{\mu})^k],$$

where $\mathbf{x}^l = x_1^{l_1} x_2^{l_2} \cdots x_d^{l_d}$ for $\mathbf{l} = (l_1, l_2, \dots, l_d) \in \mathbb{N}_0^d$. Thus,

$$Q_v(t \cdot \boldsymbol{\mu}, t) = \sum_{\mathbf{k} \leq \mathbf{v}} \binom{\mathbf{v}}{\mathbf{k}} (t \cdot \boldsymbol{\mu})^{v-k} E[(-t \cdot \boldsymbol{\mu})^k]. \quad (3.12)$$

By applying (3.12), we have

$$\begin{aligned} E[Q_v(t \cdot \boldsymbol{\mu}, t) \mid s \cdot \boldsymbol{\mu}] &= \sum_{\mathbf{k} \leq \mathbf{v}} \binom{\mathbf{v}}{\mathbf{k}} E \left[(t \cdot \boldsymbol{\mu})^{v-k} E[(-t \cdot \boldsymbol{\mu})^k \mid s \cdot \boldsymbol{\mu}] \right] \\ &= \sum_{\mathbf{k} \leq \mathbf{v}} \binom{\mathbf{v}}{\mathbf{k}} E \left[(t \cdot \boldsymbol{\mu})^{v-k} \mid s \cdot \boldsymbol{\mu} \right] E[(-t \cdot \boldsymbol{\mu})^k]. \end{aligned}$$

The result follows suitably rearranging the terms and using (3.10)

$$\begin{aligned} E[Q_v(t \cdot \boldsymbol{\mu}, t) \mid s \cdot \boldsymbol{\mu}] &= \\ &= \sum_{\mathbf{k} \leq \mathbf{v}} \binom{\mathbf{v}}{\mathbf{k}} \left\{ \sum_{\mathbf{j} \leq \mathbf{v}-\mathbf{k}} \binom{\mathbf{v}-\mathbf{k}}{\mathbf{j}} (s \cdot \boldsymbol{\mu})^j E[\{(t-s) \cdot \boldsymbol{\mu}'\}^{v-k-j}] \right\} E[(-t \cdot \boldsymbol{\mu})^k] \\ &= \sum_{\mathbf{k} \leq \mathbf{v}} \binom{\mathbf{v}}{\mathbf{k}} (s \cdot \boldsymbol{\mu})^k E[\{(t-s) \cdot \boldsymbol{\mu}' + (-t \cdot \boldsymbol{\mu})\}^{v-k}] \\ &= \sum_{\mathbf{k} \leq \mathbf{v}} \binom{\mathbf{v}}{\mathbf{k}} (s \cdot \boldsymbol{\mu})^k E[(-s \cdot \boldsymbol{\mu})^{v-k}] = Q_v(s \cdot \boldsymbol{\mu}, s). \end{aligned}$$

□

A feature of a multivariate time-space harmonic polynomial is that when \mathbf{x} is replaced by $t \cdot \boldsymbol{\mu}$ its overall evaluation is zero.

Corollary 3.7. $E[Q_v(t \cdot \boldsymbol{\mu}, t)] = 0$.

Assume

$$Q_v(\mathbf{x}, t) = \sum_{\mathbf{k} \leq \mathbf{v}} q_{\mathbf{k}}(t) \mathbf{x}^{\mathbf{k}}. \quad (3.13)$$

We now give some properties of the coefficients $q_{\mathbf{k}}(t)$.

Corollary 3.8. $q_{\mathbf{k}}(t) = \binom{\mathbf{v}}{\mathbf{k}} E[(-t.\boldsymbol{\mu})^{v-k}]$ for all $\mathbf{k} \leq \mathbf{v}$ and $q_{\mathbf{k}}(0) = 0$ for all $\mathbf{k} < \mathbf{v}$.

Proof. The first equality follows by comparing (3.13) with (3.12). For the second one, if $t = 0$ then $0.\boldsymbol{\mu} \equiv \boldsymbol{\varepsilon}$, and in particular $E[(0.\boldsymbol{\mu})^{v-k}] = E[\boldsymbol{\varepsilon}^{v-k}] = 1$ if $\mathbf{k} = \mathbf{v}$ and 0 otherwise. \square

Proposition 3.9. $q_{\mathbf{k}}(t-1) = \sum_{\mathbf{k} \leq \mathbf{j} \leq \mathbf{v}} \binom{\mathbf{j}}{\mathbf{k}} g_{\mathbf{j}} q_{\mathbf{j}}(t)$, for all $\mathbf{k} < \mathbf{v}$.

Proof. The result follows from Corollary 3.8 as

$$\begin{aligned} q_{\mathbf{k}}(t-1) &= \binom{\mathbf{v}}{\mathbf{k}} E[(-t.\boldsymbol{\mu} + \boldsymbol{\mu})^{v-k}] = \binom{\mathbf{v}}{\mathbf{k}} \sum_{\mathbf{j} \leq \mathbf{v}-\mathbf{k}} \binom{\mathbf{v}-\mathbf{k}}{\mathbf{j}} E[(-t.\boldsymbol{\mu})^{v-k-j}] g_{\mathbf{j}} \\ &= \sum_{\mathbf{k} \leq \mathbf{i} \leq \mathbf{v}} \binom{\mathbf{i}}{\mathbf{k}} g_{\mathbf{i}-\mathbf{k}} E\left[\binom{\mathbf{v}}{\mathbf{i}} (-t.\boldsymbol{\mu})^{v-i}\right]. \end{aligned}$$

\square

Corollary 3.10. $g_{\mathbf{v}} q_{\mathbf{k}}(t) = q_{\mathbf{0}}(t-1) - \sum_{\mathbf{j} < \mathbf{v}} g_{\mathbf{j}} q_{\mathbf{k}}(t)$.

Proof. The result follows from Proposition 3.9, as

$$q_{\mathbf{0}}(t-1) = \sum_{\mathbf{j} \leq \mathbf{v}} \binom{\mathbf{j}}{\mathbf{0}} q_{\mathbf{j}}(t) g_{\mathbf{j}} = \sum_{\mathbf{j} \leq \mathbf{v}} q_{\mathbf{j}}(t) g_{\mathbf{j}} = q_{\mathbf{v}}(t) g_{\mathbf{v}} + \sum_{\mathbf{j} < \mathbf{v}} q_{\mathbf{j}}(t) g_{\mathbf{j}}.$$

\square

Proposition 3.11. $g_{\mathbf{v}} = q_{\mathbf{0}}(t-1) - \sum_{\mathbf{k} < \mathbf{v}} q_{\mathbf{k}}(t) g_{\mathbf{k}}$.

Proof. From Corollary 3.8, we have

$$\sum_{\mathbf{k} < \mathbf{v}} q_{\mathbf{k}}(t) g_{\mathbf{k}} = \sum_{\mathbf{k} \leq \mathbf{v}} \binom{\mathbf{v}}{\mathbf{k}} E[(-t.\boldsymbol{\mu})^{v-k}] g_{\mathbf{k}} - g_{\mathbf{v}} = E[(-(t-1).\boldsymbol{\mu})^v] - g_{\mathbf{v}}.$$

The result follows by applying again Corollary 3.8 to $E[(-(t-1).\boldsymbol{\mu})^v]$. \square

The following theorem characterizes the coefficients of any multivariate time-space harmonic polynomial.

Theorem 3.12. *A polynomial*

$$P(\mathbf{x}, t) = \sum_{\mathbf{k} \leq \mathbf{v}} p_{\mathbf{k}}(t) \mathbf{x}^{\mathbf{k}} \tag{3.14}$$

is a time-space harmonic polynomial with respect to $\{t.\boldsymbol{\mu}\}_{t \geq 0}$ if and only if

$$p_{\mathbf{k}}(t) = \sum_{\mathbf{k} \leq \mathbf{i} \leq \mathbf{v}} \binom{\mathbf{i}}{\mathbf{k}} p_{\mathbf{k}}(0) E[(-t.\boldsymbol{\mu})^{i-\mathbf{k}}], \quad \text{for } \mathbf{k} \leq \mathbf{v}. \quad (3.15)$$

Proof. Suppose $P(\mathbf{x}, t)$ as in (3.14) with coefficients (3.15). Suitably rearranging the terms in the summation (3.15), we have

$$P(\mathbf{x}, t) = \sum_{\mathbf{k} \leq \mathbf{v}} p_{\mathbf{k}}(0) \sum_{\mathbf{i} \leq \mathbf{k}} \binom{\mathbf{k}}{\mathbf{i}} E[(-t.\boldsymbol{\mu})^{k-i}] \mathbf{x}^{\mathbf{i}} = \sum_{\mathbf{k} \leq \mathbf{v}} p_{\mathbf{k}}(0) Q_{\mathbf{k}}(\mathbf{x}, t). \quad (3.16)$$

Since $P(\mathbf{x}, t)$ is a linear combination of time-space harmonic polynomials $Q_{\mathbf{k}}(\mathbf{x}, t)$, then $P(\mathbf{x}, t)$ is in turn time-space harmonic. Vice versa, suppose $P(\mathbf{x}, t)$ in (3.14) a time-space harmonic polynomial with respect to $\{t.\boldsymbol{\mu}\}_{t \geq 0}$. Then, there exist some coefficients $\{c_{\mathbf{k}}\}$ such that

$$P(\mathbf{x}, t) = \sum_{\mathbf{k} \leq \mathbf{v}} c_{\mathbf{k}} E[(\mathbf{x} - t.\boldsymbol{\mu})^{\mathbf{k}}] = \sum_{\mathbf{k} \leq \mathbf{v}} \left(\sum_{\mathbf{k} \leq \mathbf{j} \leq \mathbf{v}} \binom{\mathbf{j}}{\mathbf{k}} c_{\mathbf{k}} E[(-t.\boldsymbol{\mu})^{j-\mathbf{k}}] \right) \mathbf{x}^{\mathbf{k}}$$

so that equality (3.15) follows. \square

Theorem 3.12 states a more general result: thanks to (3.16), any polynomial which is time-space harmonic with respect to the family $\{t.\boldsymbol{\mu}\}_{t \geq 0}$ can be expressed as a linear combination of the polynomials $Q_{\mathbf{v}}(\mathbf{x}, t)$. From (3.16), the coefficients of such a linear combination are

$$p_{\mathbf{k}}(0) = \sum_{\mathbf{k} \leq \mathbf{j} \leq \mathbf{v}} \binom{\mathbf{j}}{\mathbf{k}} p_{\mathbf{k}}(0) E[\boldsymbol{\varepsilon}^{j-\mathbf{k}}]$$

as $0.\boldsymbol{\mu} \equiv \boldsymbol{\varepsilon}$. Next section is devoted to some examples of multivariate time-space harmonic polynomials. In particular we generalize the class of Lévy-Sheffer systems and solve an open problem addressed in [11] involving multivariate Bernoulli and Euler polynomials.

3.1 Examples

Multivariate Lévy-Sheffer systems.

Definition 3.13. A sequence of multivariate polynomials $\{V_{\mathbf{k}}(\mathbf{x}, t)\}_{t \geq 0}$ is a *multivariate Lévy-Sheffer system* if

$$1 + \sum_{k \geq 1} \sum_{\substack{\mathbf{v} \in \mathbb{N}_0^d \\ |\mathbf{v}|=k}} V_{\mathbf{k}}(\mathbf{x}, t) \frac{\mathbf{z}^{\mathbf{k}}}{\mathbf{k}!} = [g(\mathbf{z})]^t \exp\{(x_1 + \cdots + x_d)[h(\mathbf{z}) - 1]\}$$

where $g(\mathbf{z})$ and $h(\mathbf{z})$ are analytic in a neighborhood of $\mathbf{z} = \mathbf{0}$ and

$$\left. \frac{\partial}{\partial z_i} h(\mathbf{z}) \right|_{\mathbf{z}=\mathbf{0}} \neq 0 \quad \text{for } i = 1, 2, \dots, d.$$

Proposition 3.14. *If $\boldsymbol{\mu}$ and $\boldsymbol{\nu}$ are d -tuples of umbral monomials such that $f(\boldsymbol{\mu}, \mathbf{z}) = g(\mathbf{z})$ and $f(\boldsymbol{\nu}, \mathbf{z}) = h(\mathbf{z})$ respectively, then*

$$V_{\mathbf{k}}(\mathbf{x}, t) = E[(t \cdot \boldsymbol{\mu} + (x_1 + \dots + x_d) \cdot \beta \cdot \boldsymbol{\nu})^{\mathbf{k}}]. \quad (3.17)$$

Proof. The result follows from Definition 3.13, since $f(t \cdot \boldsymbol{\mu}, \mathbf{z}) = f(\boldsymbol{\mu}, \mathbf{z})^t$ and the auxiliary umbra $(x_1 + \dots + x_d) \cdot \beta \cdot \boldsymbol{\nu}$ has generating function [6] $f((x_1 + \dots + x_d) \cdot \beta \cdot \boldsymbol{\nu}, \mathbf{z}) = \exp\{(x_1 + \dots + x_d)[f(\boldsymbol{\nu}, \mathbf{z}) - 1]\}$. \square

We will say that the sequence $\{V_{\mathbf{k}}(\mathbf{x}, t)\}_{t \geq 0}$ is a multivariate Lévy-Sheffer system for the pair $\boldsymbol{\mu}$ and $\boldsymbol{\nu}$. Equation (3.17) allows us to characterize the polynomial $V_{\mathbf{k}}(\mathbf{x}, t)$ as a multivariate time-space harmonic polynomial with respect to a suitable symbolic Lévy process.

To this aim we need to introduce the *multivariate compositional inverse* of a d -tuple $\boldsymbol{\nu}$. Assume $\boldsymbol{\chi}_{(i)}$ the d -tuple with all components equal to the augmentation umbra and only the i -th one equal to the singleton umbra, that is $\boldsymbol{\chi}_{(i)} = (\varepsilon, \dots, \chi, \dots, \varepsilon)$. The multivariate compositional inverse of $\boldsymbol{\nu}$ is the umbral d -tuple $\boldsymbol{\delta} = (\delta_1, \dots, \delta_d)$ such that $\delta_i \cdot \beta \cdot \boldsymbol{\nu} \equiv \boldsymbol{\chi}_{(i)}$, for $i = 1, \dots, d$. By analogy with the compositional inverse of an umbra, we denote the d -tuple $\boldsymbol{\delta}$ with the symbol $\boldsymbol{\nu}^{<-1>}$ and its i -th umbral monomial component with the symbol $\nu_i^{<-1>}$.

Theorem 3.15. *The multivariate Lévy-Sheffer polynomials for the pair $\boldsymbol{\mu}$ and $\boldsymbol{\nu}$ are time-space harmonic with respect to the symbolic multivariate Lévy process $\{t \cdot (\mu_1 \cdot \beta \cdot \nu_1^{<-1>} + \dots + \mu_d \cdot \beta \cdot \nu_d^{<-1>})\}_{t \geq 0}$.*

Proof. As $f(\boldsymbol{\chi}_{(i)}, \mathbf{z}) = 1 + z_i$ for $i = 1, \dots, d$, then $f(\boldsymbol{\mu}, \mathbf{z}) = f(\boldsymbol{\mu}, (f(\boldsymbol{\chi}_{(1)}, \mathbf{z}) - 1, \dots, f(\boldsymbol{\chi}_{(d)}, \mathbf{z}) - 1))$ so that $\boldsymbol{\mu} \equiv \mu_1 \cdot \beta \cdot \boldsymbol{\chi}_{(1)} + \dots + \mu_d \cdot \beta \cdot \boldsymbol{\chi}_{(d)}$, see [6]. Thanks to the distributive property, from (3.17)

$$\begin{aligned} & t \cdot \boldsymbol{\mu} + (x_1 + \dots + x_d) \cdot \beta \cdot \boldsymbol{\nu} \\ \equiv & t \cdot (\mu_1 \cdot \beta \cdot \boldsymbol{\chi}_{(1)} + \dots + \mu_d \cdot \beta \cdot \boldsymbol{\chi}_{(d)}) + (x_1 + \dots + x_d) \cdot \beta \cdot \boldsymbol{\nu} \\ \equiv & t \cdot (\mu_1 \cdot \beta \cdot \nu_1^{<-1>} \cdot \beta \cdot \boldsymbol{\nu} + \dots + \mu_d \cdot \beta \cdot \nu_d^{<-1>} \cdot \beta \cdot \boldsymbol{\nu}) + (x_1 + \dots + x_d) \cdot \beta \cdot \boldsymbol{\nu} \\ \equiv & [t \cdot (\mu_1 \cdot \beta \cdot \nu_1^{<-1>} + \dots + \mu_d \cdot \beta \cdot \nu_d^{<-1>}) + (x_1 + \dots + x_d)] \cdot \beta \cdot \boldsymbol{\nu}. \end{aligned} \quad (3.18)$$

Now in (3.11), set $-t \cdot \boldsymbol{\mu} = \boldsymbol{\eta}$. Then a multivariate time-space harmonic polynomial $Q_{\mathbf{v}}(\mathbf{x}, t)$ is such that $Q_{\mathbf{v}}(\mathbf{x}, t) = E[(x_1 + \eta_1)^{v_1} (x_2 + \eta_2)^{v_2} \dots (x_d +$

$\eta_d)^{v_d}]$. So any multivariate time-space harmonic polynomial is linear combination of products $E[(x_1 + \eta_1)^{v_1}(x_2 + \eta_2)^{v_2} \cdots (x_d + \eta_d)^{v_d}]$. The same results by expanding (3.18) by using (3.4) and by observing that

$$V_k(\mathbf{x}, t) \simeq \{[(t.\mu_1.\beta.\nu_1^{\langle -1 \rangle} + x_1) + \cdots + (t.\mu_d.\beta.\nu_d^{\langle -1 \rangle} + x_d)].\beta.\boldsymbol{\nu}\}^k.$$

□

Multivariate Hermite polynomials. Let us consider the multivariate nonstandard Brownian motion $\{\mathbf{X}_t\}_{t \geq 0}$ such that $\mathbf{X}_t = C \mathbf{B}_t$, where C is a $d \times d$ matrix, whose determinant is not zero, and $\{\mathbf{B}_t\}_{t \geq 0}$ is the multivariate standard Brownian motion in \mathbb{R}^d [19]. The moment generating function of $\{\mathbf{X}_t\}_{t \geq 0}$ is

$$\varphi_t(\mathbf{z}) = \exp\left(\frac{t}{2} \mathbf{z} \Sigma \mathbf{z}^T\right), \quad \Sigma = CC^T. \quad (3.19)$$

The multivariate nonstandard Brownian motion $\{\mathbf{X}_t\}_{t \geq 0}$ is a special multivariate Lévy process. Indeed, as shown in [9], a multivariate Lévy process admits a different symbolic representation with respect to $t.\boldsymbol{\mu}$, if one prefers to highlight the role played by its multivariate cumulants. Indeed any d -tuple $\boldsymbol{\mu}$ is such that $\boldsymbol{\mu} \equiv \beta.\mathbf{c}\boldsymbol{\mu}$ with $\mathbf{c}\boldsymbol{\mu}$ a d -tuple whose moments are cumulants of the sequence $\{g_{\mathbf{v}}\}_{\mathbf{v} \in \mathbb{N}_0^d}$. From (3.19) we have

$$f(\mathbf{c}\boldsymbol{\mu}, \mathbf{z}) = 1 + \frac{1}{2} \mathbf{z} \Sigma \mathbf{z}^T.$$

By considering the d -tuple $\boldsymbol{\delta}$ such that $f(\boldsymbol{\delta}, \mathbf{z}) = 1 + \mathbf{z} \Sigma \mathbf{z}^T / 2$, then every multivariate nonstandard Brownian motion with covariance matrix Σ is umbrally represented by the family of auxiliary umbrae $\{t.\beta.(\boldsymbol{\delta}C^T)\}_{t \geq 0}$.

There is a special family of multivariate polynomials which is strictly related to multivariate nonstandard Brownian motion: the generalized Hermite polynomials. The \mathbf{v} -th Hermite polynomial $H_{\mathbf{v}}(\mathbf{x}, \Sigma)$ is defined as

$$H_{\mathbf{v}}(\mathbf{x}, \Sigma) = (-1)^{|\mathbf{v}|} \frac{D_{\mathbf{x}}^{(\mathbf{v})} \phi(\mathbf{x}; \mathbf{0}, \Sigma)}{\phi(\mathbf{x}; \mathbf{0}, \Sigma)},$$

where $\phi(\mathbf{x}; \mathbf{0}, \Sigma)$ denotes the multivariate Gaussian density with $\mathbf{0}$ mean and covariance matrix Σ of full rank d .

We consider the polynomials $\tilde{H}_{\mathbf{v}}(\mathbf{x}, \Sigma) = H_{\mathbf{v}}(\mathbf{x}\Sigma^{-1}, \Sigma^{-1})$ which are orthogonal with respect to $\phi(\mathbf{x}; \mathbf{0}, \Sigma)$, where Σ^{-1} denotes the inverse of Σ .

Theorem 3.16. *The family $\{\tilde{H}_{\mathbf{v}}^{(t)}(\mathbf{x}, \Sigma)\}_{t \geq 0}$ of generalized multivariate Hermite polynomials is time-space harmonic with respect to the symbolic nonstandard multivariate Brownian motion $\{t.\beta.(\boldsymbol{\delta}C^T)\}_{t \geq 0}$.*

Proof. The moment generating function of $\{\tilde{H}_v^{(t)}(\mathbf{x}, \Sigma)\}_{t \geq 0}$ is [6]

$$1 + \sum_{k \geq 1} \sum_{|\mathbf{v}|=k} \tilde{H}_v^{(t)}(\mathbf{x}, \Sigma) \frac{\mathbf{x}^{\mathbf{v}}}{\mathbf{v}!} = \exp \left\{ \mathbf{x} \mathbf{z}^T - \frac{t}{2} \mathbf{z} \Sigma \mathbf{z}^T \right\}.$$

The result follows since $\exp \{\mathbf{x} \mathbf{z}^T\} = f(\mathbf{x}, \mathbf{z})$ and

$$f(-t.\beta.(\boldsymbol{\delta} C^T), \mathbf{z}) = \exp \left\{ \left[-\frac{t}{2} \mathbf{z} \Sigma \mathbf{z}^T \right] \right\},$$

so that $\tilde{H}_v^{(t)}(\mathbf{x}, \Sigma) = E[(\mathbf{x} - t.\beta.(\boldsymbol{\delta} C^T))^{\mathbf{v}}]$. \square

From Corollary 3.7 we also have $E[\tilde{H}_v^{(t)}(t.\beta.(\boldsymbol{\delta} C^T), \Sigma)] = 0$.

Corollary 3.17. $\tilde{H}_v^{(t)}(\mathbf{x}, \Sigma) = E[(\mathbf{x} - 1.\beta.[\boldsymbol{\delta}(t^{1/2} C^T)])^{\mathbf{v}}]$.

Proof. The result follows from Theorem 3.16, since

$$\begin{aligned} \exp \left\{ -\frac{t}{2} \mathbf{z} \Sigma \mathbf{z}^T \right\} &= \exp \left\{ -\frac{t}{2} \mathbf{z} C C^T \mathbf{z}^T \right\} = \left(\exp \left\{ f[\boldsymbol{\delta}, \mathbf{z}(t^{1/2} C)] - 1 \right\} \right)^{-1} \\ &= \left(f(\beta.[\boldsymbol{\delta}(t^{1/2} C^T)], \mathbf{z}) \right)^{-1} = f(-1.\beta.[\boldsymbol{\delta}(t^{1/2} C^T)], \mathbf{z}). \end{aligned}$$

\square

Multivariate Bernoulli polynomials. Multivariate Bernoulli polynomials are umbrally represented by umbral polynomials involving multivariate Lévy processes [11]. Indeed, let ι be the Bernoulli umbra, that is the umbra whose moments are the Bernoulli numbers. The *multivariate Bernoulli umbra* $\boldsymbol{\iota}$ is the d -tuple (ι, \dots, ι) . For all $\mathbf{v} \in \mathbb{N}_0^d$ and $t \geq 0$, the multivariate Bernoulli polynomial of order \mathbf{v} is

$$B_v^{(t)}(\mathbf{x}) = E[(\mathbf{x} + t.\boldsymbol{\iota})^{\mathbf{v}}].$$

Theorem 3.18. *The family $\{B_v^{(t)}(\mathbf{x})\}_{t \geq 0}$ of multivariate Bernoulli polynomials is time-space harmonic with respect to the family $\{-t.\boldsymbol{\iota}\}_{t \geq 0}$.*

In particular, we have $E[B_v^{(t)}(-t.\boldsymbol{\iota})] = E\left\{ \mathcal{B}_v^{(t)}[t.(-1.\boldsymbol{\iota})] \right\} = 0$. The auxiliary umbra $-t.\boldsymbol{\iota}$ is the symbolic version of a Lévy process. Indeed, $-1.\boldsymbol{\iota}$ is the umbral counterpart of a d -tuple identically distributed to (U, \dots, U) , where U is a uniform r.v. on the interval $(0, 1)$.

Multivariate Euler polynomials. Multivariate Euler polynomials are umbrally represented by umbral polynomials involving multivariate Lévy processes [11]. Let η be the Euler umbra, that is the umbra whose moments are the Euler numbers. Then the *multivariate Euler umbra* $\boldsymbol{\eta}$ is the d -tuple (η, \dots, η) . For all $\mathbf{v} \in \mathbb{N}_0^d$ and $t \in \mathbb{R}$, the multivariate Euler polynomial of order \mathbf{v} is

$$\mathcal{E}_{\mathbf{v}}^{(t)}(\mathbf{x}) = E \left\{ \left(\mathbf{x} + \frac{1}{2}[t \cdot (\boldsymbol{\eta} - \mathbf{u})] \right)^{\mathbf{v}} \right\}$$

with $\mathbf{u} = (u, \dots, u)$ a vector of unity umbrae and $\boldsymbol{\eta}$ the multivariate Euler umbra.

Theorem 3.19. *The family $\{\mathcal{E}_{\mathbf{v}}^{(t)}(\mathbf{x})\}_{t \geq 0}$ of multivariate Euler polynomials is time-space harmonic with respect to the family $\{\frac{1}{2}[t \cdot (\mathbf{u} - 1 \cdot \boldsymbol{\eta})]\}_{t \geq 0}$.*

The auxiliary umbra $\frac{1}{2}[t \cdot (\mathbf{u} - 1 \cdot \boldsymbol{\eta})]$ is the symbolic version of a Lévy process. Indeed, $\frac{1}{2}(\mathbf{u} - 1 \cdot \boldsymbol{\eta})$ is the umbral counterpart of a d -tuple identically distributed to (Y, \dots, Y) , where Y is a Bernoulli r.v. of parameter $1/2$.
