## ABSTRACT

We describe an algorithm to compute the number of points over finite fields on a broad class of modular curves: we consider quotients  $X_H/W$  for  $H$  a subgroup of  $\mathrm{GL}_2(\mathbb{Z}/n\mathbb{Z})$  such that for each prime  $p$  dividing  $n$ , the subgroup  $H$  at  $p$  is either a Borel subgroup, a Cartan subgroup, or the normalizer of a Cartan subgroup of  $\mathrm{GL}_2(\mathbb{Z}/p^e\mathbb{Z})$ , and for  $W$  any subgroup of the Atkin-Lehner involutions of  $X_H$ . We applied our algorithm to more than ten thousand curves of genus up to 50, finding more than one hundred record-breaking curves, namely curves  $X/\mathbb{F}_q$  with genus  $g$  that improve the previously known lower bound for the maximum number of points over  $\mathbb{F}_q$  of a curve with genus  $g$ . As a key technical tool for our computations, we prove the generalization of Chen’s isogeny to all the Cartan modular curves of composite level.

### 1. Introduction

Finding among the algebraic curves of a fixed genus, the ones with the largest number of points over a finite field of fixed cardinality, is an interesting effort in algebraic geometry and number theory which also has applications in coding theory (see for example [27, Section 8.4]). The Weil bound prescribes the inequality

$$\#C(\mathbb{F}_q) \leq q + 1 + 2g\sqrt{q},$$

where  $\#C(\mathbb{F}_q)$  is the number of points over a finite field  $\mathbb{F}_q$ , with  $q$  being a prime power, of a nonsingular, projective, absolutely irreducible curve  $C$  of genus  $g$ .

Let  $q$  be a fixed prime power. As it is shown in [29] and [31], the previous estimate cannot be sharp for  $g$  large since

$$N_g(\mathbb{F}_q) \leq g(\sqrt{q} - 1) + o(g), \quad \text{for } g \rightarrow +\infty,$$

where  $N_g(\mathbb{F}_q) := \max_{C \text{ of genus } g} \#C(\mathbb{F}_q)$ . Several sequences  $\{C_n\}_{n \in \mathbb{N}}$  of algebraic curves over  $\mathbb{F}_q$  with increasing genus  $g_n$ , have been found to achieve the asymptotic bound  $\lim_{n \rightarrow +\infty} \frac{\#C_n(\mathbb{F}_q)}{g_n} = \sqrt{q} - 1$ . Among these sequences, one of the most classical example is obtained by taking modular curves  $X_0(m)$  with certain increasing levels  $m$  and counting supersingular points over a field  $\mathbb{F}_q$ , where  $q$  is a square, see [28]. Concerning curves with small genus, the website [30] is devoted to collect the full list of known upper bounds  $M_g(\mathbb{F}_q)$  and lower bounds  $L_g(\mathbb{F}_q)$  for  $N_g(\mathbb{F}_q)$ , when  $g \leq 50$  and for fields of characteristic less than 100 with small cardinality. Notice that  $M_g(\mathbb{F}_q)$  and  $L_g(\mathbb{F}_q)$  depend on the current state of the art in this line of research.

In this paper we look at this question concentrating on a large class of modular curves. Namely, we consider modular curves  $X_H$  associated to a subgroup  $H$  of  $\text{GL}_2(\mathbb{Z}/n\mathbb{Z})$  such that, for each prime  $p$  dividing  $n$ , with maximum power  $e$ , the reduction of  $H$  modulo  $p^e$  is either a Borel subgroup, a Cartan subgroup, or the normalizer of a Cartan subgroup of  $\text{GL}_2(\mathbb{Z}/p^e\mathbb{Z})$ . We also consider quotients of these curves by Atkin-Lehner involutions  $w_p$  whenever  $H$  is a Borel subgroup at  $p$ . We give an algorithm which computes the number of points over a finite field on these modular curves, without having the equation of the curve, but only using the trace of Hecke operators acting on modular abelian varieties associated to weight 2 newforms invariant under the congruence subgroup  $\Gamma_0(m)$ . Numerical approximations of these traces can be computed with the methods described in [3] and they have been collected for  $m \leq 10000$  in the database available at [18].

We applied our algorithm to these modular curves over small finite fields of characteristic less than 20 using data available on [18]. Furthermore, in September 2022 we compared our results with the best known curves available on the database [30] and we found many improvements that we list in the final section of this paper.

To make the computation, we prove that the Jacobian of the modular curves  $X_H$  we are considering, are isogenous to a product of modular abelian varieties associated to

weight 2 newforms invariant under the congruence subgroup  $\Gamma_0(m)$ . We give explicitly this factorization of the Jacobian (Theorem 3.8), generalizing results of [8], [15], [9], [11].

The idea to use these types of modular curves builds on recent work on computing equations, rational points, and automorphism groups for such curves, as for example [19], [23], [12], [11], [13], [10], [22], [4], [5], [16], [1]. Another algorithm has been recently devised for computing the number of points on  $X_H$  for a general  $H$ , see [26, Section 5]. Their method does not make use of the factorization of the Jacobian of the modular curve up to isogeny, but they rather can obtain it case by case as a consequence of the computation of the number of points of the curves over many fields of different characteristic [26, Section 6].

The paper is organized as follows. In Section 2 we introduce the definitions related to the modular curves we are considering. In Section 3 we describe the Jacobians of our curves, up to isogeny, explicitly in terms of the Jacobian of Borel modular curves. In Section 4 we discuss the algorithm we use to compute the number of points over finite fields.

In Section 5 we give asymptotic results to estimate the number of  $\mathbb{F}_q$ -points on our curves when the genus  $g$  is large. Finally, in Section 6 and in the Appendix, we collect the results obtained. In particular, for every choice of  $g$  and  $\mathbb{F}_q$ , we list in the Appendix the curve with the largest number of points among the ones we considered, and in Section 6, for the convenience of the reader, we collect all the examples which improve the previously known lower bounds  $L_g(\mathbb{F}_q)$ .

## 2. Modular curves of mixed type

Let  $n$  be a positive integer. For each subgroup  $H$  of  $\mathrm{GL}_2(\mathbb{Z}/n\mathbb{Z})$  with surjective determinant, we define

$$\Gamma_H := \{\gamma \in \mathrm{SL}_2(\mathbb{Z}) : \gamma^T \pmod{n} \text{ lies in } H\}.$$

Let  $\mathbb{H} = \{\tau \in \mathbb{C} : \mathrm{Im}(\tau) > 0\}$  be the complex upper half-plane and denote by  $\mathbb{H}^* = \mathbb{H} \cup \mathbb{P}^1(\mathbb{Q})$  the extended complex upper half-plane. We define the modular curve associated to  $H$ :

$$X_H := \Gamma_H \backslash \mathbb{H}^*.$$

For a more detailed reference about this construction see [11, Section 1]. In the following, we choose a non-square element  $\xi \in (\mathbb{Z}/p^e\mathbb{Z})^\times$  when  $p$  is an odd prime and  $e$  is a positive integer. We define the following subgroups of  $\mathrm{GL}_2(\mathbb{Z}/p^e\mathbb{Z})$  for every prime  $p$ :

$$B^0(p^e) := \left\{ \begin{pmatrix} a & 0 \\ c & d \end{pmatrix}, a, c, d \in \mathbb{Z}/p^e\mathbb{Z}, \quad ad \not\equiv 0 \pmod{p} \right\};$$

$$C_s(p^e) := \left\{ \begin{pmatrix} a & 0 \\ 0 & d \end{pmatrix}, a, d \in (\mathbb{Z}/p^e\mathbb{Z})^\times \right\};$$

$$\begin{aligned}
 C_s^+(p^e) &:= C_s(p^e) \cup \left\{ \begin{pmatrix} 0 & b \\ c & 0 \end{pmatrix}, b, c \in (\mathbb{Z}/p^e\mathbb{Z})^\times \right\}; \\
 C_{ns}(2^e) &:= \left\{ \begin{pmatrix} a & b \\ b & a+b \end{pmatrix}, a, b \in \mathbb{Z}/2^e\mathbb{Z}, (a, b) \not\equiv (0, 0) \pmod{2} \right\}; \\
 C_{ns}^+(2^e) &:= C_{ns}(2^e) \cup \left\{ \begin{pmatrix} a & a-b \\ b & -a \end{pmatrix}, a, b \in \mathbb{Z}/2^e\mathbb{Z}, (a, b) \not\equiv (0, 0) \pmod{2} \right\}; \\
 C_{ns}(p^e) &:= \left\{ \begin{pmatrix} a & b\xi \\ b & a \end{pmatrix}, a, b \in \mathbb{Z}/p^e\mathbb{Z}, (a, b) \not\equiv (0, 0) \pmod{p} \right\}, \quad \text{if } p \text{ is odd}; \\
 C_{ns}^+(p^e) &:= C_{ns}(p^e) \cup \left\{ \begin{pmatrix} a & b\xi \\ -b & -a \end{pmatrix}, a, b \in \mathbb{Z}/p^e\mathbb{Z}, (a, b) \not\equiv (0, 0) \pmod{p} \right\}, \quad \text{if } p \text{ is odd}; \\
 B_r(p^e) &:= \left\{ \begin{pmatrix} a & bp^r \\ cp^{r+1} & d \end{pmatrix}, a, b, c, d \in \mathbb{Z}/p^e\mathbb{Z}, ad \not\equiv 0 \pmod{p} \right\}, \\
 &\text{for } r = 0, 1, \dots, e - 1; \\
 T_r(p^e) &:= \left\{ \begin{pmatrix} a & bp^r \\ cp^r & d \end{pmatrix}, a, b, c, d \in \mathbb{Z}/p^e\mathbb{Z}, ad - bcp^{2r} \in (\mathbb{Z}/p^e\mathbb{Z})^\times \right\}.
 \end{aligned}$$

We remark that  $T_e(p^e) = C_s(p^e)$  and that  $C_s(p^e), C_{ns}(p^e)$  are respectively a split and a non-split Cartan subgroup of  $GL_2(\mathbb{Z}/p^e\mathbb{Z})$  and, with the exception of  $C_s^+(2^e)$ , the groups  $C_s^+(p^e), C_{ns}^+(p^e)$  are the corresponding normalizers inside  $GL_2(\mathbb{Z}/p^e\mathbb{Z})$ .

Given  $n_0, n_{0+}, n_s, n_{s+}, n_{ns}, n_{ns+}$  pairwise coprime positive integers such that  $n = n_0 n_{0+} n_s n_{s+} n_{ns} n_{ns+}$ . By Chinese Remainder Theorem we have  $GL_2(\mathbb{Z}/n\mathbb{Z}) \cong \prod_{i=1}^r GL_2(\mathbb{Z}/p_i^{e_i}\mathbb{Z})$ . We look at the subgroups of  $GL_2(\mathbb{Z}/n\mathbb{Z})$  of the following form

$$H \cong \prod_{i=1}^r H_{p_i}, \quad \text{where } H_{p_i} = \begin{cases} B^0(p_i^{e_i}), & \text{if } p_i \mid n_0 n_{0+}, \\ C_s(p_i^{e_i}), & \text{if } p_i \mid n_s, \\ C_s^+(p_i^{e_i}), & \text{if } p_i \mid n_{s+}, \\ C_{ns}(p_i^{e_i}), & \text{if } p_i \mid n_{ns}, \\ C_{ns}^+(p_i^{e_i}), & \text{if } p_i \mid n_{ns+}. \end{cases} \tag{2.1}$$

Then we define our modular curves of mixed type as

$$X(n_0, n_{0+}, n_s, n_{s+}, n_{ns}, n_{ns+}) := X_H / \langle w_{p_i}, \text{ for every prime } p_i \text{ dividing } n_{0+} \rangle, \tag{2.2}$$

$$X(n_0, n_{0+}, n_{ns}, n_{ns+}) := X(n_0, n_{0+}, 1, 1, n_{ns}, n_{ns+}), \tag{2.3}$$

where  $w_{p_i}$  denotes the Atkin-Lehner operator associated to  $p_i$ . Let  $n = p_1^{e_1} \cdots p_r^{e_r}$  be the prime factorization of  $n$ . We also define, for every positive integer  $n$ , the congruence subgroup

$$\Gamma_0(n) := \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL_2(\mathbb{Z}) : \begin{pmatrix} a & b \\ c & d \end{pmatrix} \equiv \begin{pmatrix} * & * \\ 0 & * \end{pmatrix} \pmod{n} \right\},$$

we denote the  $\mathbb{C}$ -vector space of the cusp forms of weight 2 invariant under  $\Gamma_0(n)$  by  $\mathcal{S}_2(\Gamma_0(n))$  and by  $\mathcal{S}_2^{\text{new}}(\Gamma_0(n))$  the subspace generated by the newforms. We define the modular curve:

$$X_0(n) := \Gamma_0(n) \backslash \mathbb{H}^*.$$

We also denote the Jacobian of this curve by  $J_0(n) := \text{Jac}(X_0(n))$  and its new part by  $J_0^{\text{new}}(n)$ , which is the factor of  $J_0(n)$  isogenous to the abelian variety associated to  $\mathcal{S}_2^{\text{new}}(\Gamma_0(n))$ .

**Remark 2.4.** There is an isomorphism of algebraic curves

$$X(n_0, n_{0+}, n_s, n_{s+}, n_{ns}, n_{ns+}) \cong X(n_0 n_s^2, n_{0+} n_{s+}^2, n_{ns}, n_{ns+}).$$

Indeed, writing the above curves respectively as  $X_{H_1}/W_1 = \Gamma_1 \backslash \mathbb{H}^*$  and  $X_{H_2}/W_2 = \Gamma_2 \backslash \mathbb{H}^*$ , for  $\Gamma_1, \Gamma_2$  subgroups of  $\text{PGL}_2^{\det > 0}(\mathbb{R}) = \text{Aut}(\mathbb{H})$ , the group  $\Gamma_1$  can be obtained conjugating  $\Gamma_2$  firstly by  $\begin{pmatrix} 0 & -1 \\ n_s n_{s+} & 0 \end{pmatrix}$  and then conjugating again by a suitable matrix in  $\text{SL}_2(\mathbb{Z})$ .

### 3. Jacobians of modular curves of mixed type and generalization of Chen’s isogeny

With the notation introduced in Section 2, in this section we show that the Jacobian of the curves  $X(n_0, n_{0+}, n_s, n_{s+}, n_{ns}, n_{ns+})$  is isogenous to a product of Atkin-Lehner quotients of  $J_0^{\text{new}}(m)$  for suitable levels  $m$ . This generalizes a set of results beginning with Chen’s work in [8] who proved the existence of an isogeny between the Jacobian of  $X_{C_{ns}(p)}$  and  $J_0^{\text{new}}(p^2)$ , and between  $X_{C_{ns+}(p)}$  and  $J_0^{\text{new}}(p^2)/\langle w_p \rangle$ . This type of isogenies are often referred to as *Chen’s isogenies*. We start with the key lemma where we discuss separately the four Cartan cases.

**Lemma 3.1.** *Let  $n > 1$  be an integer and let  $H < \text{GL}_2(\mathbb{Z}/n\mathbb{Z})$  be a subgroup. We use the following notation:*

$$J_0^{\text{new}}(n)^{w_{p_1} w_{p_2} \dots w_{p_k}} := J_0^{\text{new}}(n) / \langle w_{p_1}, w_{p_2}, \dots, w_{p_k} \rangle,$$

for  $p_1, \dots, p_k$  distinct primes dividing  $n$  and  $w_{p_j}$  the Atkin-Lehner involution associated to  $p_j$ , for  $j = 1, \dots, k$ . Then we have:

(1) *If  $H = C_s(n) := \prod_{i=1}^r C_s(p_i^{e_i})$ , then*

$$\text{Jac}(X_H) = J_s(n) \sim \prod_{d|n^2} J_0^{\text{new}}(d)^{\sigma_0\left(\frac{n^2}{d}\right)}, \tag{3.2}$$

where  $\sigma_0(m)$  is the number of positive divisors of an integer  $m$ .

(2) If  $H = C_s^+(n) := \prod_{i=1}^r C_s^+(p_i^{e_i})$ , then

$$\text{Jac}(X_H) = J_s^+(n) \sim \prod_{d|n^2} J_0^{\text{new}}(d)^{\sigma_0^*\left(\frac{n^2}{d}\right)}, \tag{3.3}$$

where  $\sigma_0^*$  is the function defined by

$$\sigma_0^*(p^f) := \begin{cases} \frac{1}{2}(f + 1), & \text{if } f \text{ is odd,} \\ \frac{f}{2} + w_p, & \text{if } f \text{ is even,} \end{cases}$$

for a prime  $p$  and a positive integer  $f$ , and  $\sigma_0^*(m_1 m_2) = \sigma_0^*(m_1) \sigma_0^*(m_2)$ , for  $m_1, m_2$  coprime positive integers.

(3) If  $H = C_{\text{ns}}(n) := \prod_{i=1}^r C_{\text{ns}}(p_i^{e_i})$ , then

$$\text{Jac}(X_H) = J_{\text{ns}}(n) \sim \prod_{d|n} J_0^{\text{new}}(d^2). \tag{3.4}$$

(4) If  $H = C_{\text{ns}}^+(n) := \prod_{i=1}^r C_{\text{ns}}^+(p_i^{e_i})$ , then

$$\text{Jac}(X_H) = J_{\text{ns}}^+(n) \sim \prod_{d|n} J_0^{\text{new}}(d^2)^{w_{p_1} \dots w_{p_s}}, \tag{3.5}$$

where  $p_1, \dots, p_s$  are all the primes dividing  $d$ .

**Proof.** Part 1. We have

$$\text{Jac}(X_H) = J_s(n) \cong J_0(n^2),$$

because  $W_n^{-1} \Gamma_{C_s(n)}(n) W_n = \Gamma_0(n^2)$ , where  $W_n := \begin{pmatrix} 0 & -1 \\ n & 0 \end{pmatrix}$ , and

$$J_0(n^2) \sim \prod_{d|n^2} J_0^{\text{new}}(d)^{\sigma_0\left(\frac{n^2}{d}\right)},$$

because of classical Atkin-Lehner theory about the oldforms (see [14]).

Part 2. Let  $n = p_1^{e_1} \dots p_k^{e_k}$  be the prime factorization of  $n$  and let  $W_Q$ , for a positive integer  $Q$ , be the matrix defined in [2, after Lemma 7]. We have

$$\text{Jac}(X_H) = J_s^+(n) \cong J_0(n^2)^{w_{p_1} \dots w_{p_k}},$$

because  $\begin{pmatrix} 0 & -1 \\ n & 0 \end{pmatrix} \Gamma_{C_s^+(n)} \begin{pmatrix} 0 & -1 \\ n & 0 \end{pmatrix}^{-1}$  is congruent to  $\left\langle \Gamma_0(n^2), W_{p_1^{2e_1}}, \dots, W_{p_k^{2e_k}} \right\rangle$  modulo scalar matrices. Then

$$J_0(n^2)^{w_{p_1} \dots w_{p_k}} \sim \prod_{d|n^2} J_0^{\text{new}}(d)^{\sigma_0^*\left(\frac{n^2}{d}\right)},$$

because of Atkin-Lehner theory (see [2, Equations 5.1 and 5.2]).

Part 3. Let  $n = p_1^{e_1} \dots p_k^{e_k}$  be the prime factorization. For each  $c = p_1^{f_1} \dots p_k^{f_k}$ , we define

$$K(c) := \prod_{j=1}^k K_j(p_j^{f_j}) < \text{GL}_2(\mathbb{Z}/c\mathbb{Z}), \quad \text{with} \quad K_j(p_j^{f_j}) := \begin{cases} T_{\frac{f_j}{2}}(p_j^{e_j}), & \text{if } f_j \text{ is even,} \\ B_{\frac{f_j-1}{2}}(p_j^{e_j}), & \text{if } f_j \text{ is odd.} \end{cases}$$

Then, using the machinery in [15] together with [11, Proposition 3.2], we get

$$\text{Jac}(X_H) = J_{\text{ns}}(n) \sim \prod_{c|n^2} \text{Jac}(X_{K(c)})^{\varepsilon(c)m(c)},$$

where the functions  $\varepsilon(c)$  and  $m(c)$  are defined by

$$\varepsilon(p^f) := (-1)^f, \quad \text{and} \quad m(p^f) := \begin{cases} 1, & \text{if } p^f || n^2, \\ 2, & \text{otherwise,} \end{cases} \tag{3.6}$$

for a prime power dividing  $n^2$  and by  $\varepsilon(d_1 d_2) = \varepsilon(d_1)\varepsilon(d_2)$  and  $m(d_1 d_2) = m(d_1)m(d_2)$  for  $d_1, d_2$  coprime divisors of  $n^2$ . (For example if  $n^2 = p^2 q^2$  and  $c = p = p^1 q^0$ , then  $m(c) = m(p^1)m(q^0) = 4$ .) Moreover, we have

$$\prod_{c|n^2} \text{Jac}(X_{K(c)})^{\varepsilon(c)m(c)} \cong \prod_{c|n^2} J_0(c)^{\varepsilon(c)m(c)},$$

because  $\Gamma_{K(c)}$  and  $\Gamma_0(c)$  are conjugate, as explained in [11, proof of Theorem 3.8]. Then we have

$$\prod_{c|n^2} J_0(c)^{\varepsilon(c)m(c)} \sim \prod_{c|n^2} \prod_{d|c} J_0^{\text{new}}(d)^{\varepsilon(c)m(c)\sigma_0(\frac{c}{d})},$$

because of classical Atkin-Lehner theory about the oldforms (see [14]). Last equality:

$$\prod_{c|n^2} \prod_{d|c} J_0^{\text{new}}(d)^{\varepsilon(c)m(c)\sigma_0(\frac{c}{d})} = \prod_{d|n} J_0^{\text{new}}(d^2),$$

follows by

$$\begin{aligned} \prod_{c|n^2} \prod_{d|c} J_0^{\text{new}}(d)^{\varepsilon(c)m(c)\sigma_0(\frac{c}{d})} &= \prod_{d|n^2} \prod_{d|c|n^2} J_0^{\text{new}}(d)^{\varepsilon(c)m(c)\sigma_0(\frac{c}{d})} = \\ &= \prod_{d|n^2} J_0^{\text{new}}(d)^{\sum_{d|c|n^2} \varepsilon(c)m(c)\sigma_0(\frac{c}{d})}; \end{aligned}$$

and, if  $n = p_1^{e_1} \dots p_k^{e_k}$  and  $d = p_1^{g_1} \dots p_k^{g_k}$  and  $c = p_1^{f_1} \dots p_k^{f_k}$  are the prime factorizations of  $n, d, c$ , we have

$$\begin{aligned} \sum_{d|c|n^2} \varepsilon(c)m(c)\sigma_0\left(\frac{c}{d}\right) &= \sum_{f_1=g_1}^{2e_1} \dots \sum_{f_k=g_k}^{2e_k} \varepsilon(p_1^{f_1} \dots p_k^{f_k})m(p_1^{f_1} \dots p_k^{f_k})\sigma_0\left(p_1^{f_1-g_1} \dots p_k^{f_k-g_k}\right) = \\ &= \prod_{j=1}^k \sum_{f_j=g_j}^{2e_j} \varepsilon(p_j^{f_j})m(p_j^{f_j})\sigma_0\left(p_j^{f_j-g_j}\right) = \prod_{j=1}^k \left(2e_j - g_j + 1 + \sum_{f_j=g_j}^{2e_j-1} (-1)^{f_j} 2(f_j - g_j + 1)\right) = \\ &= \prod_{j=1}^k \left(2e_j - g_j + 1 + 2 \sum_{f_j=g_j}^{2e_j-1} (-1)^{f_j} f_j + 2(1 - g_j) \sum_{f_j=g_j}^{2e_j-1} (-1)^{f_j}\right) = \prod_{j=1}^k \left(\frac{1}{2}(1 + (-1)^{g_j})\right) = \\ &= \begin{cases} 1, & \text{if } g_1 \equiv \dots \equiv g_k \equiv 0 \pmod{2}, \\ 0, & \text{otherwise,} \end{cases} \end{aligned}$$

where in the fifth equality we used

$$\sum_{i=a}^{b-1} x^i = \frac{x^a - x^b}{1 - x} \quad \text{and} \quad \sum_{i=a}^{b-1} ix^{i-1} = \frac{x^a - x^b}{(1 - x)^2} + \frac{ax^{a-1} - bx^{b-1}}{1 - x},$$

hence

$$\prod_{d|n^2} J_0^{\text{new}}(d)^{\sum_{d|c|n^2} \varepsilon(c)m(c)\sigma_0\left(\frac{c}{d}\right)} = \prod_{d|n} J_0^{\text{new}}(d^2).$$

Part 4. Given the factorization  $n = p_1^{e_1} \dots p_k^{e_k}$ , for each  $c = p_1^{f_1} \dots p_k^{f_k}$ , we define

$$K'(c) := \prod_{j=1}^k K'_j(p_j^{f_j}) \in \text{GL}_2(\mathbb{Z}/c\mathbb{Z}), \quad \text{with } K'_j(p_j^{f_j}) := \begin{cases} T_{\frac{f_j}{2}}(p_j^{e_j}), & \text{if } f_j \neq 2e_j \text{ and even,} \\ C_s^+(p_j^{e_j}), & \text{if } f_j = 2e_j, \\ B_{\frac{f_j-1}{2}}(p_j^{e_j}), & \text{if } f_j \text{ is odd.} \end{cases}$$

Then, using the machinery explained in [15], together with [9, Theorem 1.1] and its extension to the even case described in Section 3 and in the appendix of [11], we get

$$\text{Jac}(X_H) = J_{\text{ns}}^+(n) \sim \prod_{c|n^2} \text{Jac}(X_{K'(c)})^{\varepsilon(c)},$$

where  $\varepsilon$  is defined as in the proof of Part 3.

Then, defining the matrices  $W_Q$ , for a positive integer  $Q$ , as in [2, after Lemma 7] and since  $\begin{pmatrix} 0 & -1 \\ m & 0 \end{pmatrix} \Gamma_{K'(c)} \begin{pmatrix} 0 & -1 \\ m & 0 \end{pmatrix}^{-1}$  is congruent to  $\left\langle \Gamma_0(c), W_{\frac{f_j}{2}} \text{ for } p_j|c \text{ s.t. } f_j = 2e_j \right\rangle$  modulo scalar matrices, where  $m$  is such that  $c = m^2 \prod_{\substack{j=1 \\ f_j \text{ odd}}}^k p_j$ , we have

$$\prod_{c|n^2} \text{Jac}(X_{K'(c)})^{\varepsilon(c)} \cong \prod_{c|n^2} J_0(c)^{\varepsilon(c)} \Pi^{w_{p_j}},$$

where

$$\prod' w_{p_j} := \prod_{\substack{p_j | c \text{ s.t.} \\ f_j = 2e_j}} w_{p_j}.$$

Then

$$\prod_{c|n^2} J_0(c)^{\varepsilon(c)\prod' w_{p_j}} \sim \prod_{c|n^2} \prod_{d|c} J_0^{\text{new}}(d)^{\varepsilon(c)\sigma'_0(\frac{c}{d})},$$

is similar to Parts 1 and 2, where

$$\sigma'_0(p^f) := \begin{cases} \sigma_0^*(p^f), & \text{if } p^f \parallel \frac{n^2}{d}, \\ \sigma_0(p^f), & \text{otherwise,} \end{cases} \tag{3.7}$$

for a prime power dividing  $\frac{n^2}{d}$  and  $\sigma'_0(d_1 d_2) = \sigma'_0(d_1)\sigma'_0(d_2)$  for  $d_1, d_2$  coprime divisors of  $\frac{n^2}{d}$ . Last equality:

$$\prod_{c|n^2} \prod_{d|c} J_0^{\text{new}}(d)^{\varepsilon(c)\sigma'_0(\frac{c}{d})} = \prod_{d|n} J_0^{\text{new}}(d^2)^{w_{p_1} \dots w_{p_k}},$$

follows by

$$\begin{aligned} \prod_{c|n^2} \prod_{d|c} J_0^{\text{new}}(d)^{\varepsilon(c)\sigma'_0(\frac{c}{d})} &= \prod_{d|n^2} \prod_{d|c|n^2} J_0^{\text{new}}(d)^{\varepsilon(c)\sigma'_0(\frac{c}{d})} = \\ &= \prod_{d|n^2} J_0^{\text{new}}(d)^{\sum_{d|c|n^2} \varepsilon(c)\sigma'_0(\frac{c}{d})}; \end{aligned}$$

and, if  $d = p_1^{g_1} \dots p_k^{g_k}$  is the prime factorization of  $d$ , we have

$$\begin{aligned} \sum_{d|c|n^2} \varepsilon(c)\sigma'_0\left(\frac{c}{d}\right) &= \sum_{f_1=g_1}^{2e_1} \dots \sum_{f_k=g_k}^{2e_k} \varepsilon(p_1^{f_1} \dots p_k^{f_k})\sigma'_0\left(p_1^{f_1-g_1} \dots p_k^{f_k-g_k}\right) = \\ &= \prod_{j=1}^k \sum_{f_j=g_j}^{2e_j} \varepsilon(p_j^{f_j})\sigma'_0\left(p_j^{f_j-g_j}\right) = \prod_{j=1}^k \left( \sigma_0^*\left(p_j^{2e_j-g_j}\right) + \sum_{f_j=g_j}^{2e_j-1} (-1)^{f_j}(f_j-g_j+1) \right) = \\ &= \prod_{j=1}^k \left( \sigma_0^*\left(p_j^{2e_j-g_j}\right) + \sum_{f_j=g_j}^{2e_j-1} (-1)^{f_j} f_j + (1-g_j) \sum_{f_j=g_j}^{2e_j-1} (-1)^{f_j} \right) = \\ &= \prod_{j=1}^k \left( \sigma_0^*\left(p_j^{2e_j-g_j}\right) - e + \frac{1}{4} \left( (-1)^{g_j} - 1 + 2g_j \right) \right) = \end{aligned}$$

$$= \begin{cases} \prod_{j=1}^k w_{p_j}, & \text{if } g_1 \equiv \dots \equiv g_k \equiv 0 \pmod{2}, \\ 0, & \text{otherwise,} \end{cases}$$

where in the fifth equality we used

$$\sum_{i=a}^{b-1} x^i = \frac{x^a - x^b}{1 - x} \quad \text{and} \quad \sum_{i=a}^{b-1} ix^{i-1} = \frac{x^a - x^b}{(1 - x)^2} + \frac{ax^{a-1} - bx^{b-1}}{1 - x},$$

hence

$$\prod_{d|n^2} J_0^{\text{new}}(d)^{\sum_{d|c|n^2} \varepsilon(c) \sigma'_0(\frac{c}{d})} = \prod_{d|n} J_0^{\text{new}}(d^2)^{w_{p_1} \dots w_{p_k}}. \quad \square$$

**Theorem 3.8.** Let  $X := X(n_0, n_{0+}, n_s, n_{s+}, n_{ns}, n_{ns+})$  be as in Equation (2.2), then

$$\text{Jac}(X) \sim \prod_{d|N} J_0^{\text{new}}(d_0 d_{0+} d_s d_{s+} d_{ns}^2 d_{ns+}^2) \sigma_0^* \left( \frac{n_0 n_s^2}{d_0 d_s} \right) \sigma_0^* \left( \frac{n_{0+} n_{s+}^2}{d_{0+} d_{s+}} \right) \prod_{p \in \mathcal{P}(d_{ns+})} w_p, \quad (3.9)$$

where  $N := n_0 n_{0+} n_s^2 n_{s+}^2 n_{ns} n_{ns+}$  and  $d := d_0 d_{0+} d_s d_{s+} d_{ns} d_{ns+}$ , with  $d_0 \mid n_0, d_{0+} \mid n_{0+}, d_s \mid n_s^2, d_{s+} \mid n_{s+}^2, d_{ns} \mid n_{ns}, d_{ns+} \mid n_{ns+}$ , and

$$J_0^{\text{new}}(p_1^{e_1} p_2^{e_2} \dots p_k^{e_k})^{w_{p_1} w_{p_2} \dots w_{p_k}} := J_0^{\text{new}}(p_1^{e_1} p_2^{e_2} \dots p_k^{e_k}) / \langle w_{p_1}, w_{p_2}, \dots, w_{p_k} \rangle,$$

for  $p_1, \dots, p_k$  distinct primes and  $w_{p_j}$  is the Atkin-Lehner involution associated to  $p_j$ , for  $j = 1, \dots, k$ ; moreover  $\mathcal{P}(m)$  is the set of prime divisors of an integer  $m$  and  $\sigma_0(m)$  is the number of positive divisors of  $m$  and  $\sigma_0^*$  is the function defined by

$$\sigma_0^*(p^f) := \begin{cases} \frac{1}{2}(f + 1), & \text{if } f \text{ is odd,} \\ \frac{f}{2} + w_p, & \text{if } f \text{ is even,} \end{cases}$$

for a prime  $p$  and a positive integer  $f$ , and  $\sigma_0^*(m_1 m_2) = \sigma_0^*(m_1) \sigma_0^*(m_2)$ , for  $m_1, m_2$  coprime positive integers.

**Proof.** This is a natural extension of the previous lemma and the argument is the same. Given  $c_{ns}$  and  $c_{ns+}$  divisors of  $n_{ns}^2$  and  $n_{ns+}^2$  respectively, for each  $c := n_0 n_{0+} n_s n_{s+} c_{ns} c_{ns+}$ , we define

$$K(c) := \prod_{\substack{p^f \parallel c \\ p \text{ prime}}} K(p^f),$$

where, if  $e$  is the  $p$ -adic valuation of  $n$ , we define

$$K(p^f) := \begin{cases} B^0(p^f), & \text{if } p|n_0n_{0+}, \\ C_s(p^f), & \text{if } p|n_s, \\ C_s^+(p^f), & \text{if } p|n_{s+}, \\ B_{\frac{f-1}{2}}(p^e), & \text{if } p|c_{ns}c_{ns+} \text{ and if } f \text{ is odd,} \\ T_{\frac{f}{2}}(p^e), & \text{if } p|c_{ns}c_{ns+} \text{ and } f \text{ is even and } f \neq 2e, \\ C_s(p^e), & \text{if } p|c_{ns} \text{ and } f = 2e, \\ C_s^+(p^e), & \text{if } p|c_{ns+} \text{ and } f = 2e. \end{cases}$$

Again, using the machinery explained in [15], together with the representation theoretic results in [9] and [11], and defining  $\varepsilon, m, \sigma'_0$  as in Equations (3.6) and (3.7), we find that

$$\begin{aligned} \text{Jac}(X_H)^{\prod w_{p_{0+}}} &\sim \\ &\sim \prod_{\substack{c_{ns}|n_{ns}^2 \\ c_{ns+}|n_{ns+}^2}} \text{Jac}(X_{K(n_0n_{0+}n_s n_{s+} c_{ns}c_{ns+})})^{\varepsilon(c_{ns})\varepsilon(c_{ns+})m(c_{ns})} \prod w_{p_{0+}} \cong \\ &\cong \prod_{\substack{c_{ns}|n_{ns}^2 \\ c_{ns+}|n_{ns+}^2}} J_0(n_0n_{0+}n_s^2n_{s+}^2c_{ns}c_{ns+})^{\varepsilon(c_{ns})\varepsilon(c_{ns+})m(c_{ns})} \prod w_{p_{0+}} \prod w_{p_{s+}} \prod' w_{p_{ns+}} \sim \\ &\sim \prod_{\substack{c_{ns}|n_{ns}^2 \\ c_{ns+}|n_{ns+}^2}} \prod_{d|N} J_0^{\text{new}}(d)^{\varepsilon(c_{ns})\varepsilon(c_{ns+})m(c_{ns})\sigma_0\left(\frac{n_0}{d_0}\right)\sigma_0^*\left(\frac{n_{0+}}{d_{0+}}\right)\sigma_0\left(\frac{n_s^2}{d_s}\right)\sigma_0^*\left(\frac{n_{s+}^2}{d_{s+}}\right)\sigma_0\left(\frac{c_{ns}}{d_{ns}}\right)\sigma'_0\left(\frac{c_{ns+}}{d_{ns+}}\right)} = \\ &= \prod_{d|N} J_0^{\text{new}}(d_0d_{0+}d_s d_{s+}d_{ns}^2d_{ns+}^2)^{\sigma_0\left(\frac{n_0}{d_0}\right)\sigma_0^*\left(\frac{n_{0+}}{d_{0+}}\right)\sigma_0\left(\frac{n_s^2}{d_s}\right)\sigma_0^*\left(\frac{n_{s+}^2}{d_{s+}}\right)} \prod w_{p_{ns+}}, \end{aligned}$$

where  $d$  and  $N$  are defined in the statement of the theorem and the product  $\prod w_{p_{0+}}$  varies over all the primes  $p_{0+}$  dividing  $n_{0+}$ , the product  $\prod w_{p_{s+}}$  varies over all the primes  $p_{s+}$  dividing  $c_{s+}$ , the product  $\prod w_{p_{ns+}}$  varies over all the primes  $p_{ns+}$  dividing  $n_{ns+}$  and the product  $\prod' w_{p_{ns+}}$  varies over all the primes  $p_{ns+}$  such that  $v_{p_{ns+}}(c_{ns+}) = v_{p_{ns+}}(n_{ns+}^2)$ , where  $v_p(m)$  is the exponent of the prime  $p$  in the prime factorization of  $m$ .  $\square$

**4. Computing the number of points**

Let  $p$  and  $\ell$  be distinct primes. Let  $C$  be a smooth, projective, algebraic curve over  $\mathbb{Q}$  with good reduction over  $\mathbb{F}_p$ . Let  $\text{Ta}_\ell(\text{Jac}(C))$  be the Tate module of  $C$ , i.e., the inverse limit of the  $\ell^m$ -torsion group  $\text{Jac}(C)[\ell^m]$ , and let  $V_\ell = \text{Ta}_\ell(\text{Jac}(C)) \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell$  be the  $\mathbb{Q}_\ell$ -vector space associated to  $\text{Ta}_\ell(\text{Jac}(C))$ . The trace of the Frobenius automorphism  $\text{Frob}_{p^k}$  acting on  $V_\ell$  satisfies:

$$\text{tr}(\text{Frob}_{p^k}|V_\ell) = p^k + 1 - \#C(\mathbb{F}_{p^k}), \tag{4.1}$$

for every positive integer  $k$ . (see [21, Theorem 11.1]). When  $C$  is a modular curve associated to a group of matrices containing the scalar matrices, the Eichler-Shimura relation (see [14, Theorem 8.7.2]) implies that the trace of Frobenius can be obtained from a linear combination of traces of Hecke operators, as we explain in Section 5.

We are interested in applying Equation (4.1) when  $C = X(n_0, n_{0+}, n_s, n_{s+}, n_{ns}, n_{ns+})$  as in Equation (2.2) and  $p$  does not divide  $n = n_0 n_{0+} n_s n_{s+} n_{ns} n_{ns+}$ . Using Theorem 3.8, the number of points over  $\mathbb{F}_p$  can be computed in terms of the eigenvalues of the Hecke operator  $T_p \in \text{End}(J_0^{\text{new}}(d))$ , whose level  $d$  divides  $n$ . By [14, Theorem 6.6.6], we have that  $J_0^{\text{new}}(d)$  is isogenous to a direct sum  $\bigoplus_f A_f^{\sigma_0(d/d')}$  of Abelian varieties  $A_f$  associated to the Galois orbits of the normalized eigenforms  $f \in \mathcal{S}_2(\Gamma_0(d'))$ , where  $d' \mid d$ . In the following part of this section we explain how to compute  $\text{tr}(\text{Frob}_p|V_\ell)$  explicitly when  $C = X_H$ . This, by Equation (4.1) above, allows to compute the number of points of  $X_H$  on  $\mathbb{F}_p$ . Finally, we explain how to compute the number of points of  $X_H$  on every finite field (not only prime fields). The following lemma is well known, but we report the proof for convenience of the reader.

**Lemma 4.2.** *Let  $n$  be a positive integer, let  $p, \ell$  be distinct primes not dividing  $n$  and let  $V_\ell = \text{Ta}_\ell(J_0(n)_{\mathbb{F}_p}) \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell$  be the  $\mathbb{Q}_\ell$ -vector space associated to the Tate module of  $X_0(n)_{\mathbb{F}_p}$ . Then*

$$\text{tr}_{\mathbb{T}}(\text{Frob}_p|V_\ell) = T_p,$$

where  $T_p$  is the Hecke operator associated to the prime  $p$  and the trace is taken on  $V_\ell$  as  $\mathbb{T}_{\mathbb{Q}_\ell}$ -module with  $\mathbb{T}_{\mathbb{Q}_\ell} := \mathbb{T}_{\mathbb{Z}} \otimes_{\mathbb{Z}} \mathbb{Q}_\ell$  and  $\mathbb{T}_{\mathbb{Z}}$  denotes the Hecke algebra  $\mathbb{Z}[T_n : n > 0]$ .

**Proof.** We have that  $V_\ell$  is a free rank 2 module over  $\mathbb{T}_{\mathbb{Q}_\ell}$  (see [14, Lemma 9.5.3]). Consider the Weil pairing  $\langle \cdot, \cdot \rangle : V_\ell \times V_\ell \rightarrow \mathbb{Q}_\ell(1)$ , see [20, before Lemma 16.2, p. 132] where we identify  $J_0(n)$  with its dual variety via the principal polarization. Let  $V_\ell^*$  be the dual module of  $V_\ell$  where for every linear operator  $T : V_\ell \rightarrow V_\ell$  we have the dual action on  $V_\ell^*$ , i.e.,  $T\varphi := \varphi \circ T$ , for every  $\varphi \in V_\ell^*$ . Let  $\Phi : V_\ell \rightarrow V_\ell^*$  be the isomorphism sending  $x$  in the map  $\Phi_x : V_\ell \rightarrow \mathbb{Q}_\ell$  defined by  $\Phi_x(y) := \langle y, x \rangle$ . Each Hecke operator  $T_n$  is self-adjoint with respect to the Weil pairing, see Lemma 4.3 below. This implies that  $\Phi$  commutes with the natural action of  $\mathbb{T}_{\mathbb{Q}_\ell}$  on each side, i.e.,  $\Phi$  is an isomorphism of  $\mathbb{T}_{\mathbb{Q}_\ell}$ -modules.

The Verschiebung  $\text{Ver}_p = [p]\text{Frob}_p^{-1}$  is the dual isogeny of  $\text{Frob}_p$  on Jacobians and it is the adjoint of  $\text{Frob}_p$  with respect to Weil pairing, in fact:  $\langle x, \text{Ver}_p(y) \rangle = \langle x, [p]\text{Frob}_p^{-1}(y) \rangle = \langle x, \text{Frob}_p^{-1}(y) \rangle^p = \text{Frob}_p(\langle x, \text{Frob}_p^{-1}(y) \rangle) = \langle \text{Frob}_p(x), \text{Frob}_p(\text{Frob}_p^{-1}(y)) \rangle = \langle \text{Frob}_p(x), y \rangle$ . Hence  $\Phi \circ \text{Frob}_p = \text{Ver}_p \circ \Phi$ . This implies that  $\text{tr}_{\mathbb{T}}(\text{Frob}_p|V_\ell) = \text{tr}_{\mathbb{T}}(\text{Ver}_p|V_\ell^*)$ . But, with respect to a fixed basis on  $V_\ell$  and its dual basis on  $V_\ell^*$ , the matrix of  $\text{Ver}_p$  on  $V_\ell^*$  is the transpose of the matrix of  $\text{Ver}_p$  on  $V_\ell$ , so  $\text{tr}_{\mathbb{T}}(\text{Frob}_p|V_\ell) = \text{tr}_{\mathbb{T}}(\text{Ver}_p|V_\ell)$ . Applying the trace to the Eichler-Shimura relation  $\text{Frob}_p + \text{Ver}_p = T_p$  (see [14, Theorem 8.7.2]), we get  $2\text{tr}_{\mathbb{T}}(\text{Frob}_p|V_\ell) = \text{tr}_{\mathbb{T}}(T_p|V_\ell) = 2T_p$  and, hence  $\text{tr}_{\mathbb{T}}(\text{Frob}_p|V_\ell) = T_p$ .  $\square$

**Lemma 4.3.** *For all pairwise coprime positive integers  $N, n, \ell$ , with  $\ell$  prime, the Hecke operator  $T_n$  is self-adjoint with respect to the Weil pairing on  $J_0(N)[\ell^m]$ .*

**Proof.** Since  $T_n$  can be written as a polynomial in the operators  $T_p$  for primes  $p$  dividing  $n$  and all these  $T_p$ 's commute with each other, then it is enough to treat the case where  $n = p$  is prime.

We focus on the action of  $T_p$  on divisors supported on non-cuspidal points. Indeed, since the number of cusps is finite, each element of  $J_0(N)$  can be represented as a divisor supported in the non-cuspidal locus. We recall that the non-cuspidal points of  $X_0(N)$  parametrize data  $(E, G)$ , where  $E$  is an elliptic curve and  $G$  is a cyclic subgroup of order  $N$  of  $E[N]$  and the non-cuspidal points of  $X_0(Np)$  parametrize data  $(E, \varphi: E \rightarrow E', G)$ , for  $E, G$  as before and  $\varphi$  an isogeny of degree  $p$ . With this notation, let  $p_1, p_2: X_0(Np) \rightarrow X_0(N)$  be the maps defined by

$$p_1(E, \varphi: E \rightarrow E', G) = (E, G), \quad p_2(E, \varphi: E \rightarrow E', G) = (E', \varphi(G)),$$

and extended by continuity on the whole curve. Then  $T_p = (p_2)_* p_1^*$  as an endomorphism of the Jacobian.

We recall that for each non-constant map of curves  $f: C \rightarrow C'$ , the maps  $f^*$  and  $f_*$  between the two Jacobians are adjoint with respect to the Weil pairings. Indeed, given divisors  $D, D'$  respectively on  $C, C'$  that define  $N$ -torsion points in the respective Jacobians and such that  $f_*(D)$  is disjoint from  $D'$ , take rational functions  $g, g'$  such with  $\text{div}(g) = ND$  and  $\text{div}(g') = ND'$ , so that

$$\langle D, f^* D' \rangle = \frac{g(f^* D')}{(g' \circ f)(D)} = \frac{(\text{Norm}_f g)(D')}{(g'(f_*(D)))} = \langle f_* D, D' \rangle,$$

where  $\langle, \rangle$  denotes the Weil pairing on the  $N$ -torsion subgroup and  $\text{Norm}_f$  is the norm of the finite extension of function fields  $f^\#: K(C') \hookrightarrow K(C)$ , namely for each rational function  $h$  on  $C'$  we denote  $\text{Norm}_f(h) = \det_{K(C)}(\cdot h: K(C') \rightarrow K(C')) \in K(C)$ .

As a consequence of the above general fact, the adjoint of  $T_p$  is  $T_p^* = (p_1)_* p_2^*$ , i.e., it is induced by the transposed correspondence of  $T_p$ . Hence, to prove our statement, it is enough proving that the image of the map  $(p_1, p_2): X_0(Np) \rightarrow X_0(N) \times X_0(N)$  is symmetric. Indeed, given  $x = (E, G), y = (E', G')$  in  $X_0(N) \times X_0(N)$ , the point  $(x, y)$  lies in the image of  $(p_1, p_2)$  if and only if there exists an isogeny  $\varphi: E \rightarrow E'$  of degree  $p$  such that  $\varphi(G) = G'$ . If this happens, then the dual isogeny  $\hat{\varphi}: E' \rightarrow E$  sends  $G'$  into  $G$ , since  $G = [p]G = \hat{\varphi}(\varphi(G)) = \hat{\varphi}(G')$ . In other words whenever  $(x, y)$  lies in the image of  $(p_1, p_2)$ , then  $(y, x)$  lies in the same image, i.e., the image of  $(p_1, p_2)$  is symmetric.  $\square$

The following proposition explains how to compute  $\text{tr}(\text{Frob}_p|V_\ell)$  explicitly when the abelian variety considered is not necessarily a Jacobian but it is a product of  $A_f$  for  $f \in \mathcal{S}_2^{\text{new}}(\Gamma_0(n_f))$ , where  $n_f \in \mathbb{Z}_{>0}$  is the level of  $f$ . It implies the case we are interested in:  $C = X_H$  for  $H$  as described in the statement of Theorem 3.8.

**Proposition 4.4.** *Let  $\mathcal{F}$  be a finite subset of the set of the Galois orbits of normalized eigenforms of  $\bigcup_{n>0} \mathcal{S}_2^{\text{new}}(\Gamma_0(n))$ , and let  $J := \prod_{[f] \in \mathcal{F}} A_f^{m_f}$ , where  $A_f$  is the abelian variety associated to Galois orbit of  $f$  (see [14, Definition 6.6.3]) and  $m_f \in \mathbb{Z}_{>0}$ . Moreover, let  $V_\ell = \text{Ta}_\ell(J) \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell$  be the  $\mathbb{Q}_\ell$ -vector space associated to the Tate module of  $J$ . Then the characteristic polynomial of  $\text{Frob}_p$  acting on  $V_\ell$  is*

$$\prod_{[f] \in \mathcal{F}} \prod_{h \in [f]} (x^2 - a_p(h)x + p)^{m_f},$$

where  $a_p(h)$  is the  $p$ -th Fourier coefficient of  $h$ .

**Proof.** It is enough to treat the case  $\mathcal{F} = \{[f]\}$  for  $f$  an eigenform of level  $n$ . Let

$$S := \bigoplus_{h \in [f]} \mathbb{C}h \subset \mathcal{S}_2^{\text{new}}(\Gamma_0(n)),$$

and let  $\mathbb{T}$  be the Hecke algebra of  $A_f$  defined as the maximal quotient of the Hecke algebra  $\mathbb{T}'$  of  $J_0(n)$  such that the action of  $\mathbb{T}'$  on  $A_f$  acts through  $\mathbb{T}$ . Also, for each ring  $R$ , let  $\mathbb{T}_R := \mathbb{T} \otimes R$ .

By [14, Lemma 9.5.3],  $V_\ell$  is a free module of rank 2 over  $\mathbb{T}_{\mathbb{Q}_\ell}$ , and the characteristic polynomial of  $\text{Frob}_p$  as a  $\mathbb{T}_{\mathbb{Q}_\ell}$ -linear endomorphism is  $x^2 - T_p x + p$ . Indeed, by Lemma 4.2 this characteristic polynomial is of the form  $x^2 - T_p x + a$  for a certain  $a \in \mathbb{T}_{\mathbb{Q}_\ell}$ . Since  $\mathbb{T}_{\mathbb{Q}_\ell}$  acts faithfully on  $V_\ell$ , the element  $a$  is the unique element of  $\mathbb{T}_{\mathbb{Q}_\ell}$  such that  $\text{Frob}_p^2 - T_p \text{Frob}_p + a = 0$ , and  $a = p$  satisfies this property because, by Eichler-Shimura Relation and denoting by  $\text{Ver}_p$  the Verschiebung operator, we have

$$\begin{aligned} \text{Frob}_p^2 - T_p \text{Frob}_p + p &= \text{Frob}_p^2 - (\text{Frob}_p + \text{Ver}_p) \text{Frob}_p + \text{Frob}_p \text{Ver}_p = \\ &= (\text{Frob}_p - \text{Ver}_p)(\text{Frob}_p - \text{Frob}_p) = 0. \end{aligned}$$

In particular, the characteristic polynomial of  $\text{Frob}_p$  as a  $\mathbb{Q}_\ell$ -linear endomorphism of  $V_\ell$  is

$$\begin{aligned} &\det_{\mathbb{Q}_\ell[x]}(\text{Frob}_p - x|V_\ell \otimes_{\mathbb{Q}_\ell} \mathbb{Q}_\ell[x]) \\ &= \text{Norm}_{\mathbb{T}_{\mathbb{Q}_\ell[x]}/\mathbb{Q}_\ell[x]} \left( \det_{\mathbb{T}_{\mathbb{Q}_\ell[x]}}(\text{Frob}_p - x|V_\ell \otimes_{\mathbb{Q}_\ell} \mathbb{Q}_\ell[x]) \right) = \\ &= \text{Norm}_{\mathbb{T}_{\mathbb{Q}_\ell[x]}/\mathbb{Q}_\ell[x]}(x^2 - T_p x + p) = \text{Norm}_{\mathbb{T}_{\mathbb{Q}[x]}/\mathbb{Q}[x]}(x^2 - T_p x + p) = \\ &= \text{Norm}_{\mathbb{T}_{\mathbb{C}[x]}/\mathbb{C}[x]}(x^2 - T_p x + p), \end{aligned}$$

where, given a ring extension  $A \subset B$  such that  $B$  is a finite, free  $A$ -module, we denote  $\text{Norm}_{B/A}(t) := \det_A(\cdot t: B \rightarrow B)$ , i.e., the determinant of the multiplication by  $t$  inside  $B$  as a  $A$ -module endomorphism. Since  $S$  is a free  $\mathbb{T}_{\mathbb{C}}$ -module of rank 1, then  $S \cong \mathbb{T}_{\mathbb{C}}$  as  $\mathbb{T}_{\mathbb{C}}$ -modules, hence,

$$\text{Norm}_{\mathbb{T}_{\mathbb{C}[x]}/\mathbb{C}[x]}(x^2 - T_p x + p) = \det_{\mathbb{C}[x]}(x^2 - T_p x + p | S \otimes_{\mathbb{C}} \mathbb{C}[x]) = \prod_{h \in [f]} (x^2 - a_p(h)x + p),$$

where the last equality is true because the elements  $h \in [f]$  are a basis of eigenvectors for  $T_p$  in  $S$ , with eigenvalue  $a_p(h)$ .  $\square$

Using Theorem 3.8 and Formula 4.2 above we can compute  $\#X(n_0, n_{0+}, n_{\text{ns}}, n_{\text{ns}+})(\mathbb{F}_q)$  for all prime power  $q = p^k$  not dividing  $n = n_0 n_{0+} n_{\text{ns}} n_{\text{ns}+}$ . We concentrate on these cases because of the isomorphism of Remark 2.4. The algorithm runs as follows:

**Algorithm 4.5.** *Computing the number of points of  $X(n_0, n_{0+}, n_{\text{ns}}, n_{\text{ns}+})$  over  $\mathbb{F}_q$ .*

- (1) For every  $d|n$ , compute  $d_0 := \text{gcd}(n_0, d)$  and similarly  $d_0^+, d_{\text{ns}}$  and  $d_{\text{ns}+}$  and let  $D := d_0 d_0^+ d_{\text{ns}}^2 d_{\text{ns}+}^2$ .
- (2) For every  $d|n$ , choose a basis  $\mathcal{B}(d)$  of new eigenforms of level  $D$  and let  $\mathcal{B} := \bigcup_{d|n} \mathcal{B}(d)$  be the union of these bases.
- (3) For every  $d | n$  and for each prime  $\ell | d_{\text{ns}}^+$ , compute the eigenvalue of  $f \in \mathcal{B}(d)$  with respect to the Atkin-Lehner operator  $w_\ell$  and discard from  $\mathcal{B}$  the  $f$ 's with eigenvalue  $-1$  (these data are available on the database [18] for  $D \leq 10000$ ).
- (4) Compute the Hecke eigenvalue  $a_p(f)$  for every  $f \in \mathcal{B}$  (these data are available on the database [18] for  $D \leq 10000$ ).
- (5) For each  $f \in \mathcal{B}$ , compute  $m_f := \sigma_0(n_0/d_0) \tilde{\sigma}_0(n_{0+}/d_{0+}, f)$ , where  $\sigma_0(m)$  is the number of positive divisors of  $m$  and  $m \mapsto \tilde{\sigma}_0(m, f)$  is the multiplicative function defined by

$$\tilde{\sigma}_0(p^r, f) := \begin{cases} \frac{1}{2}(r + 1), & \text{if } r \text{ is odd,} \\ \frac{r}{2} + 1, & \text{if } r \text{ is even and } w_p f = f, \\ \frac{r}{2}, & \text{if } r \text{ is even and } w_p f = -f. \end{cases}$$

- (6) If  $k = 1$ , then compute Frobenius traces acting on  $A_f$ :  $\text{tr}(\text{Frob}_p | A_f) = \sum_{h \in [f]} a_p(h)$ , where  $[f]$  is the Galois orbit of  $f$ .
- (7) If  $k > 1$ , then compute the (complex) roots  $\alpha(h)$  and  $\beta(h)$  of quadratic the polynomial  $x^2 - a_p(h)x + p = 0$ , for each  $h \in [f]$ . Then compute  $\text{tr}(\text{Frob}_q | A_f) = \sum_{h \in [f]} (\alpha(h)^k + \beta(h)^k)$ , using Equation (4.1)
- (8) Finally,  $\#X(n_0, n_{0+}, n_{\text{ns}}, n_{\text{ns}+})(\mathbb{F}_q) = q + 1 - \sum_{[f]} m_f \text{tr}(\text{Frob}_q | A_f)$ , where the sum is taken over the distinct orbits for  $f \in \mathcal{B}$ .

**Example 4.6.** We compute the number of points of  $X(1, 163, 1, 1, 1, 1) = X_0^+(163)$  over  $\mathbb{F}_{2^2}$  without using the explicit equation in [19]. Consider the space of cusp forms  $\mathcal{S}_2^{\text{new}}(\Gamma_0(163))$ . This space has dimension 13 and let  $f_1, f_2, f_3$  be representatives under the Galois action. The class of  $f_1$  has just one element, the class of  $f_2$  has 5 elements and the class of  $f_3$  has 7 elements. Since  $f_3$  has negative eigenvalue, its class is discarded.

We compute  $m_{f_1} = m_{f_2} = 1$ , hence the genus of  $X_0^+(163)$  is 6. The Hecke eigenvalues are  $a_2(f_1) = 0$  and  $a_2(h) \approx -2.711, -2.484, -1.634, 0.163, 1.666$ , for  $h \in [f_2]$ . We consider the polynomial  $(x^2 - a_2(f_1)x + 2) \prod_{h \in [f_2]} (x^2 - a_2(h)x + 2)$ . We denote its roots by  $\alpha_j$  and  $\beta_j$ , where  $\alpha_1 \approx 1.414i, \alpha_2 \approx -1.355 + 0.402i, \alpha_3 \approx -1.242 + 0.675i, \alpha_4 \approx -0.817 + 1.154i, \alpha_5 \approx 0.081 + 1.411i, \alpha_6 \approx 0.833 + 1.1425i$  and  $\beta_j = \bar{\alpha}_j$  is the complex conjugated of  $\alpha_j$ . Hence  $\#X_0^+(163)(\mathbb{F}_{2^2}) = 4 + 1 - \sum_{j=1}^6 (\alpha_j^2 + \beta_j^2) = 4 + 1 + 5 = 10$ .

**Example 4.7.** We compute the number of points of  $X(1, 17, 1, 1, 1, 3)$  over  $\mathbb{F}_2$ . We have to consider the space of cusp forms  $\mathcal{S}_2^{\text{new}}(\Gamma_0(D))$  at levels  $D = 1, 9, 17, 153$ . The first two spaces are trivial. The third one has dimension 1, but the corresponding representative under the Galois action must be discarded, since the eigenvalue of Atkin-Lehner operator  $w_{17}$  is  $-1$ . Finally, the last space has 5 representatives under the Galois action and we denote them by  $f_1, f_2, f_3, f_4, f_5$ . Four of these classes should be discarded since they have at least a negative eigenvalue. We denote by  $f$  the unique representative whose both eigenvalues of  $w_3$  and  $w_{17}$  are positive. Then  $A_f$  has dimension 1 and  $m_f = \sigma_0(1)\sigma_0^*(1) = 1$ , so it follows that the genus of  $X(1, 17, 1, 1, 1, 3)$  must be 1. The eigenvalue of  $T_2$  acting on  $f$  is  $a_2(f) = -2$ . Then  $\#X(1, 17, 1, 1, 1, 3)(\mathbb{F}_2) = 2 + 1 + 2 = 5$ . This is the maximum possible value for an elliptic curve over  $\mathbb{F}_2$  according to [30].

**Example 4.8.** We compute the number of points of  $X(5, 3, 1, 1, 2, 1)$  over  $\mathbb{F}_{7^2}$ . We have to consider the space of cusp forms  $\mathcal{S}_2^{\text{new}}(\Gamma_0(D))$  at levels  $D = 1, 3, 4, 5, 12, 15, 20, 60$ . Only the spaces corresponding to  $D = 15$  and  $D = 20$  are non-trivial, more precisely,  $\mathcal{S}_2^{\text{new}}(\Gamma_0(D))$  has dimension 1 in both these cases. We denote by  $f_1$  and  $f_2$ , respectively, the corresponding representative under the Galois action. In both cases, the action under the Atkin-Lehner involution  $w_3$  gives positive eigenvalues so both  $f_1$  and  $f_2$  must be considered. Since  $m_{f_1} = \sigma_0(1)\sigma_0^*(1) = 1$  and  $m_{f_2} = \sigma_0(1)\sigma_0^*(3) = 1$ , it follows that  $X(5, 3, 1, 1, 2, 1)$  has genus 2. The eigenvalue of  $T_7$  acting on  $f_1$  and  $f_2$  are 0 and 2, respectively. Denote by  $\alpha_1, \beta_1, \alpha_2, \beta_2$  the roots of the polynomial  $(x^2 + 7)(x^2 - 2x + 7)$ . Then  $\alpha_1 \approx 2.646i, \beta_1 \approx -2.646i, \alpha_2 \approx 1 + 2.499i, \beta_2 \approx 1 - 2.499i$  and  $\#X(5, 3, 1, 1, 2, 1)(\mathbb{F}_{7^2}) = 7^2 + 1 - \sum_{i=1}^2 (\alpha_i^2 + \beta_i^2) = 49 + 1 + 24 = 74$ .

### 5. Asymptotic estimates

In this section we estimate the number of points on the reductions over prime finite fields of the curves  $X = X(n_0, n_{0+}, n_s, n_{s+}, n_{\text{ns}}, n_{\text{ns+}})$ . We start by recalling a classical formula which we then combine with estimates on the trace of Hecke operators. Notice that by Theorem 3.8, the space of regular differentials on  $X$  can be identified with a direct sum of spaces of newforms of shape  $\mathcal{S}_2^{\text{new}}(\Gamma_0(d))^W$  for  $W$  a certain group of Atkin-Lehner operators and  $d$  a suitable positive integer. In particular, this decomposition defines an action of Hecke operators on  $\Omega_{X/\mathbb{C}}^1$ .

**Proposition 5.1.** *Given  $X = X(n_0, n_{0+}, n_s, n_{s+}, n_{ns}, n_{ns+})$  and defining  $T_{p^{-1}} := 0$ , we have*

$$\#X(\mathbb{F}_{p^e}) = p^e + 1 - \text{tr}(T_{p^e} | \Omega_{X/\mathbb{C}}^1) + p \text{tr}(T_{p^{e-2}} | \Omega_{X/\mathbb{C}}^1),$$

for each integer  $e \geq 1$  and for every prime  $p$  not dividing  $n = n_0 n_{0+} n_s n_{s+} n_{ns} n_{ns+}$ .

**Proof.** Let  $\alpha_1, \dots, \alpha_g, \beta_1, \dots, \beta_g$  be the eigenvalues of the Frobenius acting on the Tate module of the Jacobian of  $X_{\mathbb{F}_p}$ . By Proposition 4.4, up to reordering, we can suppose that  $\alpha_i + \beta_i = a_p(f_i)$ , where  $f_1, \dots, f_g$  are the normalized eigenforms giving a basis of  $\Omega_{X/\mathbb{C}}^1$ . Hence because of Equation (4.1) and Proposition 4.4, it is enough to prove that

$$\alpha_i^e + \beta_i^e = a_{p^e}(f_i) - p a_{p^{e-2}}(f_i). \tag{5.2}$$

The case  $e = 1$  is true defining  $a_{p^{-1}} := 0$ . Since  $\alpha_i \beta_i = p$  (by Proposition 4.4), and  $T_{p^2} = T_p^2 - p$  (by [14, Equation (5.10)]), we have

$$a_{p^2}(f_i) - p = a_p(f_i)^2 - 2p = (\alpha_i + \beta_i)^2 - 2\alpha_i \beta_i = \alpha_i^2 + \beta_i^2,$$

which proves the case  $e = 2$ . For the inductive step we recall that on  $\Omega_{X/\mathbb{C}}^1$  we have

$$T_{p^e} - p T_{p^{e-2}} = T_p(T_{p^{e-1}} - p T_{p^{e-3}}) - p(T_{p^{e-2}} - p T_{p^{e-4}}).$$

Hence, supposing that Equation (5.2) holds for  $e-1$  and  $e-2$ , we get

$$\begin{aligned} a_{p^e}(f_i) - p a_{p^{e-2}}(f_i) &= a_p(f_i)(a_{p^{e-1}}(f_i) - p a_{p^{e-3}}(f_i)) - p(a_{p^{e-2}}(f_i) - p a_{p^{e-4}}(f_i)) \\ &= (\alpha_i + \beta_i)(\alpha_i^{e-1} + \beta_i^{e-1}) - (\alpha_i \beta_i)(\alpha_i^{e-2} + \beta_i^{e-2}) = \alpha_i^e + \beta_i^e. \quad \square \end{aligned}$$

To estimate the traces of Hecke operators on  $\mathcal{S}_2^{\text{new}}(\Gamma_0(d))^W$  for  $W$  a group of Atkin-Lehner operators, it is enough to estimate  $\text{tr}(T_p w_m | \mathcal{S}_2^{\text{new}}(\Gamma_0(d)))$  for each  $w_m \in W$ . A small remark on notation: given the prime factorization  $d = p_1^{e_1} \cdots p_r^{e_r}$ , here and in Section 3, we sometimes write  $w_{p_i}$  meaning  $w_{p_i^{e_i}}$ , while other times we use the usual notation  $w_m$  for  $m \mid d$  such that  $\text{gcd}(m, d/m) = 1$ . To estimate the trace of  $T_k w_m$ , for such a divisor  $m$  of  $d$ , we look at [7, Proposition 2.8], which states:

$$|\text{tr}(T_k w_m | \mathcal{S}_2^{\text{new}}(\Gamma_0(d))) - \delta(\sqrt{k} \in \mathbb{Z}) F(d, m)| < c_0(k + \sqrt{kd}) \sigma_0^3(d) \sigma_0(k) \log^2(4kd), \tag{5.3}$$

where  $c_0$  is an absolute constant,  $\sigma_0$  is the function counting the number of divisors of a natural number,  $\delta(\text{condition})$  is 1 if the condition is true and 0 otherwise, and

$$F(d, m) := \mu(\sqrt{m}) \frac{d}{m} \prod_{\ell \in \mathcal{P}(\frac{d}{m})} \left( 1 - \frac{1}{\ell} - \frac{\delta(\ell^2 | \frac{d}{m})}{\ell^2} + \frac{\delta(\ell^3 | \frac{d}{m})}{\ell^3} \right),$$

with  $\mathcal{P}(N)$  the set of prime divisors of an integer  $N$ , and  $\mu$  the Möbius function extended so that  $\mu(\sqrt{m}) = 0$  if  $\sqrt{m}$  is not an integer. Combining Equation (5.3) and Proposition 5.1 we get the following proposition.

**Proposition 5.4.** *There exists an absolute constant  $C$  such that, for each curve  $X = X(n_0, n_{0+}, n_s, n_{s+}, n_{ns}, n_{ns+})$  of genus  $g$  and for each prime power  $q = p^e$  coprime to  $n_0 n_{0+} n_s n_{s+} n_{ns} n_{ns+}$ , we have*

$$\begin{cases} \#X(\mathbb{F}_q) < C(q + \sqrt{gq})g^{\frac{10}{\log \log g}} p \log^3 q, & \text{if } q \text{ is not a square,} \\ |\#X(\mathbb{F}_q) - (p - 1)g| < C(q + \sqrt{gq})g^{\frac{10}{\log \log g}} p \log^3 q, & \text{if } q \text{ is a square.} \end{cases}$$

**Proof.** We start by slightly simplifying Equation (5.3): using [24, Theorem 1] to bound  $\sigma_0$ , we get

$$|\text{tr}(w_m | \mathcal{S}_2^{\text{new}}(\Gamma_0(d))) - F(d, m)| < 2c_0 d^{\frac{1}{2} + \frac{4.4}{\log \log d}} \tag{5.5}$$

when specializing to  $k = 1$  in Equation (5.3); while for  $k = r$  a prime power we have

$$|\text{tr}(T_r w_m | \mathcal{S}_2^{\text{new}}(\Gamma_0(d))) - \delta(\sqrt{r} \in \mathbb{Z})F(d, m)| < 20c_0 d^{\frac{4.4}{\log \log d}} (r + \sqrt{rd}) \log^3 r. \tag{5.6}$$

Since we are only interested in the cases where  $\mathcal{S}_2^{\text{new}}(\Gamma_0(d)) \neq 0$ , we restrict to the cases  $d \geq 11$ , hence  $\log \log d$  makes sense and is positive.

We recall that, for each finite group  $G$  acting on a finite vector space  $V$ , the linear operator  $\sum_{g \in G} g : V \rightarrow V$  has trace equal to  $\#G \dim(V^G)$ . Hence, applying Equation (5.5), for each group of the form  $W = \langle w_\ell : \ell \in \mathcal{Q} \rangle$  with  $\mathcal{Q}$  a subset of the prime divisors of  $d$ , we can write

$$\dim(J_0(d)^W) = \frac{1}{\#W} \sum_{w_m \in W} \text{tr}(w_m | \mathcal{S}_2^{\text{new}}(\Gamma_0(d))) = F(d, W) + \epsilon(d, W), \tag{5.7}$$

where  $|\epsilon(d, W)| < 2c_0 d^{\frac{1}{2} + \frac{4.4}{\log \log d}}$  and  $F(d, W)$  is defined and can be estimated as follows

$$\begin{aligned} F(d, W) &:= \frac{1}{\#W} \sum_{w_m \in W} F(d, m) = \frac{1}{\#W} \sum_{\{\ell_1, \dots, \ell_r\} \subseteq \mathcal{Q}} F(d, \ell_1^{e_{\ell_1}} \dots \ell_r^{e_{\ell_r}}) = \\ &= \frac{d}{\#W} \sum_{\{\ell_1, \dots, \ell_r\} \subseteq \mathcal{Q}} \prod_{\ell \in \{\ell_1, \dots, \ell_r\}} \frac{\mu(\ell^{e_\ell/2})}{\ell^{e_\ell}} \prod_{\substack{\ell | d \\ \ell \notin \{\ell_1, \dots, \ell_r\}}} \left(1 - \frac{1}{\ell} - \frac{\delta(\ell^2 | \frac{d}{m})}{\ell^2} + \frac{\delta(\ell^3 | \frac{d}{m})}{\ell^3}\right) = \\ &= \frac{d}{\#W} \prod_{\substack{\ell | d \\ \ell \notin \mathcal{Q}}} \left(1 - \frac{1}{\ell} - \frac{\delta(\ell^2 | \frac{d}{m})}{\ell^2} + \frac{\delta(\ell^3 | \frac{d}{m})}{\ell^3}\right) \cdot \\ &\cdot \sum_{\{\ell_1, \dots, \ell_r\} \subseteq \mathcal{Q}} \prod_{\ell \in \{\ell_1, \dots, \ell_r\}} \frac{\mu(\ell^{e_\ell/2})}{\ell^{e_\ell}} \prod_{\substack{\ell \in \mathcal{Q} \\ \ell \notin \{\ell_1, \dots, \ell_r\}}} \left(1 - \frac{1}{\ell} - \frac{\delta(\ell^2 | \frac{d}{m})}{\ell^2} + \frac{\delta(\ell^3 | \frac{d}{m})}{\ell^3}\right) = \end{aligned}$$

$$\begin{aligned}
 &= \frac{d}{\#W} \prod_{\substack{\ell|d \\ \ell \notin \mathcal{Q}}} \left( 1 - \frac{1}{\ell} - \frac{\delta(\ell^2|\frac{d}{m})}{\ell^2} + \frac{\delta(\ell^3|\frac{d}{m})}{\ell^3} \right) \\
 &\cdot \prod_{\ell \in \mathcal{Q}} \left( 1 - \frac{1}{\ell} - \frac{\delta(\ell^2|\frac{d}{m})}{\ell^2} + \frac{\delta(\ell^3|\frac{d}{m})}{\ell^3} + \frac{\mu(\ell^{e_\ell/2})}{\ell^{e_\ell}} \right) \geq \\
 &\geq \frac{d}{\sigma_0(d)} \prod_{\ell|d} \left( 1 - \frac{1}{\ell} \right) \left( 1 - \frac{1}{\ell^2} \right)^2 \geq \frac{\varphi(d)}{\sigma_0(d)} \zeta(2)^{-2} \geq c_1 d^{1 - \frac{1.2}{\log \log d}},
 \end{aligned}$$

where  $\varphi$  is the Euler’s totient function, estimated as in [17, Theorem 327], and  $\zeta$  is the Riemann zeta function. Analogously, Equation (5.6) implies that

$$\begin{aligned}
 \text{tr}(T_r | \mathcal{S}_2^{\text{new}}(\Gamma_0(d))^W) &= \frac{1}{\#W} \sum_{w_m \in W} \text{tr}(T_r w_m | \mathcal{S}_2^{\text{new}}(\Gamma_0(d))) = \tag{5.8} \\
 &= \delta(\sqrt{r} \in \mathbb{Z}) F(d, W) + \epsilon(d, W, r),
 \end{aligned}$$

with  $|\epsilon(d, W, r)| < 20c_0 d^{\frac{4.4}{\log \log d}} (r + \sqrt{rd}) \log^3 r$ .

We now look at the curve  $X$ . Using Theorem 3.8 to write  $\Omega_{X/\mathbb{C}}^1$  as a sum of spaces of the form  $\mathcal{S}_2^{\text{new}}(\Gamma_0(d))^W$  and taking linear combinations of Equations (5.8) and (5.7), we get

$$g = F + \epsilon, \quad \text{tr}(T_r | \Omega_{X/\mathbb{C}}^1) = \delta(\sqrt{r} \in \mathbb{Z}) F + \epsilon_r, \tag{5.9}$$

for

$$\begin{aligned}
 F &= \sum_d \sigma_0 \left( \frac{n_0 n_s^2}{d_0 d_s} \right) \sum_{m^2 \parallel \frac{n_0 + n_s^2}{d_0 + d_s^2}} \sigma_0^+ \left( \frac{n_0 + n_s^2}{d_0 + d_s + m^2} \right) F \left( d_0 d_{0+} d_s d_{s+} d_{\text{ns}}^2 d_{\text{ns}+}^2, \langle w_\ell : \ell | m d_{\text{ns}+} \rangle \right), \\
 \epsilon &= \sum_d \sigma_0 \left( \frac{n_0 n_s^2}{d_0 d_s} \right) \sum_{m^2 \parallel \frac{n_0 + n_s^2}{d_0 + d_s^2}} \sigma_0^+ \left( \frac{n_0 + n_s^2}{d_0 + d_s + m^2} \right) \epsilon \left( d_0 d_{0+} d_s d_{s+} d_{\text{ns}}^2 d_{\text{ns}+}^2, \langle w_\ell : \ell | m d_{\text{ns}+} \rangle \right), \\
 \epsilon_r &= \sum_d \sigma_0 \left( \frac{n_0 n_s^2}{d_0 d_s} \right) \sum_{m^2 \parallel \frac{n_0 + n_s^2}{d_0 + d_s^2}} \sigma_0^+ \left( \frac{n_0 + n_s^2}{d_0 + d_s + m^2} \right) \epsilon \left( d_0 d_{0+} d_s d_{s+} d_{\text{ns}}^2 d_{\text{ns}+}^2, \langle w_\ell : \ell | m d_{\text{ns}+} \rangle, r \right),
 \end{aligned}$$

where the external sums are indexed over  $d$  equal to the product of  $d_0, d_{0+}, d_s, d_{s+}, d_{\text{ns}}, d_{\text{ns}+}$ , which vary across the divisors respectively of  $n_0, n_{0+}, n_s^2, n_{s+}^2, n_{\text{ns}}, n_{\text{ns}+}$ , while the internal sums of the form  $\sum_{m^2 \parallel k}$  are indexed over the positive integers  $m$  such that  $m^2$  divides  $k$  and  $\text{gcd}(k, \frac{k}{m^2}) = 1$ , and finally  $\sigma_0^+$  is the multiplicative function such that  $\sigma_0^+(\ell^e) = \lceil \frac{e}{2} \rceil$  for each prime power  $\ell^e$ . Under the notation  $N = n_0 n_{0+} n_s^2 n_{s+}^2 n_{\text{ns}}^2 n_{\text{ns}+}^2$ , using [24, Theorem 1] and the previous estimates on  $F(d, W)$ ,  $\epsilon(d, W)$  and  $\epsilon(d, W, r)$ , we get

$$\begin{aligned}
 F &\geq F(N, \langle w_\ell : \ell | n_{\text{ns}^+} \rangle) \geq c_1 N^{1 - \frac{1.2}{\log \log N}}, \\
 |\epsilon| &\leq \sigma_0(N)^3 \max\{|\epsilon(d, W)| : d | N, W < \langle w_\ell : \ell | d \rangle\} < 2c_0 N^{\frac{1}{2} + \frac{7.6}{\log \log N}}, \\
 |\epsilon_r| &\leq \sigma_0(N)^3 \max\{\epsilon(d, W, r) : d | N, W < \langle w_\ell : \ell | d \rangle\} \leq 20c_0 N^{\frac{7.6}{\log \log N}} (r + \sqrt{rN}) \log^3 r.
 \end{aligned}$$

Plugging the first two bounds above into Equation (5.9), for appropriate constants  $c_2$  and  $c_3$ , we have

$$g > c_2 N^{1 - \frac{1.2}{\log \log N}}$$

that implies

$$N < c_3 g^{1 + \frac{1.4}{\log \log g}}.$$

Again using Equation (5.9) and the bounds on  $\epsilon, \epsilon_r$ , we get, for a suitable  $c_4$ , that

$$\begin{aligned}
 |\text{tr}(T_r | \Omega_{X/\mathbb{C}}^1) - \delta(\sqrt{r} \in \mathbb{Z})g| &= |\epsilon_r - \delta(\sqrt{r} \in \mathbb{Z})\epsilon| \\
 &< 2c_0 N^{\frac{1}{2} + \frac{7.6}{\log \log N}} + 20c_0 N^{\frac{7.6}{\log \log N}} (r + \sqrt{rN}) \log^3 r \\
 &< c_4 (r + \sqrt{r}g^{\frac{1}{2} + \frac{0.7}{\log \log g}}) g^{\frac{8.4}{\log \log g}} \log^3 r.
 \end{aligned}$$

This estimate, together with Proposition 5.1, implies the desired result.  $\square$

The above proposition implies that, for a fixed  $q$ , we expect a large number of points on our curves mostly for  $q = p^2$ . Anyway, the estimates are only relevant for  $N$  large with respect to  $q$ , and indeed we found records also for fields of the form  $p^5$ .

**Remark 5.10.** As first shown in [25] (see also [28, Section 1] or [6, Section 3.3]), the case  $q = p^2$  is known to provide many rational points in modular curves, thanks to the presence of supersingular points: the  $j$ -invariant of a supersingular elliptic curve  $E$  lies in  $\mathbb{F}_{p^2}$  and, up to twisting, the absolute Galois of  $\mathbb{F}_{p^2}$  acts diagonally on the torsion of  $E$ . For example, the bounds in [6, Lemma 3.20] imply that, for each congruence subgroup  $\Gamma \subset \text{SL}_2(\mathbb{Z})$ , and for each prime  $p$  coprime to the level, we have

$$X_\Gamma(\mathbb{F}_{p^2}) > (p - 1)(g_\Gamma - 1), \tag{5.11}$$

where  $g_\Gamma$  is the genus of  $X_\Gamma$ . This inequality can easily be extended to our curves. Indeed, let  $X = X(n_0, n_{0^+}, n_s, n_{s^+}, n_{\text{ns}}, n_{\text{ns}^+})$ , with genus  $g$  and let  $p$  be a prime not dividing  $n_0 n_{0^+} n_s n_{s^+} n_{\text{ns}} n_{\text{ns}^+}$ . Then we can write  $X = X_\Gamma/G$  for a suitable choice of  $\Gamma$  and of a group of automorphisms  $G$ . The Riemann-Hurwitz’s formula implies that  $g$  satisfies  $g - 1 \leq (g_\Gamma - 1)/(\#G)$ . The inclusion  $X(\mathbb{F}_{p^2}) \supset X_\Gamma(\mathbb{F}_{p^2})/G$ , together with orbit counting implies that  $X(\mathbb{F}_{p^2})$  has cardinality at least  $\#X_\Gamma(\mathbb{F}_{p^2})/\#G$ . Using also Equation (5.11) we get  $X(\mathbb{F}_{p^2}) > (p - 1)(g - 1)$ .

### 6. Greatest hits

We implemented Algorithm 4.5 and applied it to all the curves for which we could compute the number of points using the numerical data available at [18]. In Table 6.1 and Table 6.2 we list all the improved bounds, which we found, for the number of points of  $X(n_0, n_{0+}, n_{ns}, n_{ns+})$  over  $\mathbb{F}_q$ , where  $n_0 n_{0+} n_{ns}^2 n_{ns+}^2 \leq 10000$  and  $q = p^k$  is a prime power with  $p < 20$  and  $k \leq 5$ . As explained in Remark 2.4, the search along this set of curves gives the same results over the bigger set of  $X(n_0, n_{0+}, n_s, n_{s+}, n_{ns}, n_{ns+})$  curves since

$$\#X(n_0, n_{0+}, n_s, n_{s+}, n_{ns}, n_{ns+})(\mathbb{F}_q) = \#X(n_0 n_s^2, n_{0+} n_{s+}^2, 1, 1, n_{ns}, n_{ns+})(\mathbb{F}_q).$$

The entries list the genus  $g$  of the curve, the size  $q$  of the finite field, the 4-tuple  $(n_0, n_{0+}, n_{ns}, n_{ns+})$  and the number  $\#X(\mathbb{F}_q)$  of  $\mathbb{F}_q$ -points of  $X(n_0, n_{0+}, n_{ns}, n_{ns+})$ . When a lower bound  $L_g(\mathbb{F}_q)$  is not yet available, we list a curve of genus  $g$  with  $M$  points only if the corresponding upper bound satisfies  $M_g(\mathbb{F}_q) < q + 1 + \sqrt{2}(M - q - 1)$ , as it is done in the database [30] at the time of writing (September 2022).

**Table 6.1**  
Improved bounds of the form  $\#X(n_0, n_{0+}, n_{ns}, n_{ns+})(\mathbb{F}_q)$  for  $n_0 n_{0+} n_{ns}^2 n_{ns+}^2 \leq 10000$  and  $g \leq 25$ .

Data will be made available on request.

**Appendix A. More data**

In Tables [A.1](#), [A.2](#), [A.3](#), [A.4](#), [A.5](#), [A.6](#), [A.7](#) and [A.8](#), we list the maximal values that we found for the number of points of the curves  $X(n_0, n_{0+}, n_{ns}, n_{ns+})$  over  $\mathbb{F}_q$ , for  $n_0 n_{0+} n_{ns}^2 n_{ns+}^2 \leq 10000$  and  $q = p^k$  a prime power with  $p < 20$ ,  $k \leq 5$  for  $p$  odd and  $k \leq 6$  for  $p = 2$ . As in Section 6 we restrict our search to the curves  $X(n_0, n_{0+}, n_{ns}, n_{ns+})$ . The entries are of the type  $(n_0, n_{0+}, n_{ns}, n_{ns+}) \rightarrow \#X(n_0, n_{0+}, n_{ns}, n_{ns+})(\mathbb{F}_q)$  and the field is indicated only once at the top of the column. All the values that improve previous known lower bounds  $L_g(\mathbb{F}_q)$  are in bold. When a lower bound  $L_g(\mathbb{F}_q)$  is not yet available, we display in bold curves with  $M$  points only if the corresponding upper bound satisfies  $M_g(\mathbb{F}_q) < q + 1 + \sqrt{2}(M - q - 1)$ , as it is done in the database [30] at the time of writing (September 2022).

**Table A.1**

Table for  $\max\{\#X(n_0, n_0^+, n_{ns}, n_{ns^+})(\mathbb{F}_q)\}$  with  $q = 2^k$  and  $n_0 n_0^+ + n_{ns}^2 n_{ns^+} \leq 10000$ .
