Preface

This volume contains the 71 papers accepted for presentation at the workshops hosted by the 18th International Conference on Image Analysis and Processing, held in Genova, Italy, September 7–11, 2015, organized by the Istituto Italiano di Tecnologia (IIT).

The International Conference on Image Analysis and Processing (ICIAP) is a conference organized every two years by the GIRPR, the Italian group of researchers affiliated with the IAPR. The aim of these conferences is to bring together researchers working on image analysis, image processing, and pattern recognition from around the world.

Seven individual workshops — three one-day and four half-day — were selected by the workshop chairs, Marco Cristani and Carlo Sansone, to complement ICIAP 2015 in Genova:

- BioFor 2015, International Workshop on Recent Advances in Digital Security: Biometrics and Forensics
- CTMR 2015, Color in Texture And Material Recognition
- RHEUMA 2015, Medical Imaging in Rheumatology: Advanced Applications for the Analysis of Inflammation and Damage in the Rheumatoid Joint
- ISCA 2015, Image-Based Smart City Application
- MADiMa 2015, First International Workshop on Multimedia Assisted Dietary Management
- SBMI 2015, Scene Background Modeling and Initialization
- QoEM 2015, Workshop on Image and Video Processing for Quality of Multimedia Experience

The International Workshop on Recent Advances in Digital Security: Biometrics and Forensics (BioFor 2015) organized by Modesto Castrillón Santana, from Universidad de Las Palmas de Gran Canaria, Spain, Matthias Kirchner, from Binghamton University, USA, Daniel Riccio and Luisa Verdoliva, both from Università Federico II di Napoli, Italy, provides a forum for researchers from academia and industry to develop and foster synergies between biometrics and forensics. Attacks to biometrics systems are also becoming very frequent, and ever more sophisticated, aiming both at committing commercial frauds and acts of terrorism. A similar scenario involves the world of digital media, by now pervasive in our daily life, where images and videos can be manipulated for various evil purposes, including both crimes against intellectual property and against national security. Although the goals of biometrics and media forensics are different, they have strong similarities in purposes and tools. They both aim at supporting law enforcement and investigation, and both draw on methodologies and technologies that change and evolve on a daily basis. Increasingly, new scenarios arise where techniques designed for biometrics can be utilized for forensic purposes or

vice versa. The eight papers accepted for presentation to BioFor reflect a good scenario of the field from both the scientific and applicative point of view.

The study of texture and material recognition have a long history in image analysis and computer vision. Recent works that deal with large collections of images taken from the Internet or that exploit large-scale machine learning techniques have renewed the interest in these topics. The most relevant intuition is that features from other domains, such as object recognition, may achieve comparable or at times better performance than those achieved with features specially designed for texture and material classification. Moreover, while for some artificial materials color and texture are independent properties, for natural materials they are strongly related. Whether or not color information is useful for texture and material classification is still an open issue especially “in the wild” where imaging conditions such as lighting color and direction, orientation, sensor type, etc., are unpredictable. The Color in Texture and Material Recognition (CTMR 2015) workshop, organized by Claudio Cusano - University of Pavia, Italy, Paolo Napoletano and Raimondo Schettini - University of Milan- Bicocca, Italy, and Joost Van De Weijer - Autonomous University of Barcelona, Spain, explores these topics by providing new insights for understanding color in texture and material recognition. The seven accepted papers cover different areas, including color science, computer vision, computer graphics, and machine learning.

The aim of the RHEUMA 2015 workshop — Medical Imaging in Rheumatology: Advanced applications for the analysis of inflammation and damage in the rheumatoid Joint — is to provide an overview on the development of new medical imaging methods for the early diagnosis and therapeutic control of rheumatic musculo-skeletal diseases. The goal of the RHEUMA organizers, Silvana Dellepiane and Marco A. Cimmino - University of Genova, Italy, and Gianni Viano - Softeco Sismat S.R.L., is to promote the use of alternative techniques such as MRI and US, which can even be used in a combined manner. The workshop focuses on the development of appropriate techniques for data analysis and 2D/3D visualization, in order to increase and improve the information available to the doctor during the diagnostic process and follow-up. The results of the research can also be verified at the workshop through the presentation of experimental demonstrators and database collections of case studies that can be used as a reference for training and validation sessions. The technical program featured six accepted research papers and two invited speakers, Mikael Boesen, from the Department of Radiology and Parker Institute, Bispebjerg and Frederiksberg Hospital, Copenhagen (Denmark) and Zbisaw Taborm from the Faculty of Physics, Mathematics and Computer Science, Cracow University of Technology, Cracow (Poland).

The term “smart city” is generally used to conceptualize an urban space in which digital technologies are used to enhance quality of life while saving resource consumption. The main characteristics of a smart city are participation, cooperation, and inclusiveness of citizens, which must be engaged more effectively and actively. For this purpose, a strong integration between human, collective, and artificial intelligence is necessary in a smart city, in order to improve city performance and well-being, reducing resource consumption. Of course, ICT represent a critical aspect for smart city design and implementation and innovative solutions are necessary to monitor and improve many aspects of a city life in real time, and hence to make possible the development of knowledge-intensive collaborative activities capable of adapting

themselves to manage uncertainty and maximize the problem-solving capability of the city. The ISCA 2015 — Image- Based Smart City Application — workshop focuses on the innovative image-based applications for smart city that of course involve a wide range of key sectors including intelligent mobility, health care and active aging, energy saving, e-government, tourism, e-justice, urban safety, etc. Featuring 16 accepted papers, ISCA 2015 was organized by Giuseppe Pirlo, from the University of Bari, Italy, Donato Impedovo from Dyrectalab, Italy, and Byron Leite Dantas Bezerra from the University of Pernambuco, Brazil.

The prevention of onset and progression of diet-related acute and chronic diseases requires reliable and intuitive dietary management. The need for accurate, automatic, real-time, and personalized dietary advice has been recently complemented by the advances in computer vision and smartphone technologies, permitting the development of the first mobile food multimedia content analysis applications. The proposed solutions rely on the analysis of multimedia content captured by wearable sensors, smartphone cameras, barcode scanners, RFID readers and IR sensors, along with already established nutritional databases and often require some user input. In the field of nutritional management, multimedia not only bridges diverse information and communication technologies, but also computer science with medicine, nutrition, and dietetics. This congruence brings new challenges and opportunities on dietary management. MADiMa2015, organized by Stavroula Mougiakakou - University of Bern, Switzerland, Giovani Maria Farinella - University of Catania, Italy, and Keiji Yanai - The University of Electro-Communications, Tokyo, Japan, aimed to bring together researchers from the diverse fields of engineering, computer science, and nutrition who investigate the use of information and communication technologies for better monitoring and management of food intake. The technical program featured 19 papers, carefully selected by the Program Committee, as well as two invited speakers, Prof. Edward Sazonov from the University of Alabama (USA) and Gerald Cultot, Research Programme Officer of the European Commission.

In scene analysis, the availability of an initial background model that describes the scene without foreground objects is the prerequisite, or at least can be of help, for many applications video surveillance, video segmentation, video compression, video inpainting, privacy protection for videos, and computational photography. The aim of the Scene Background and Modeling Initialization — SBMI 2015 — Workshop is to bring together researchers interested in scene background modeling and initialization (also known as bootstrapping, background estimation, background reconstruction, initial background extraction, or background generation) in different application areas, in order to disseminate their most recent research results, to advocate and promote the research into scene background modeling and initialization, to discuss rigorously and systematically potential solutions and challenges, to promote new collaborations among researchers working in different application areas, and to share innovative ideas and solutions for exploiting the potential synergies emerging from the integration of different application domains. Jointly organized by Lucia Maddalena, from the National Research Council, Italy, and Thierry Bouwmans, from the Université De La Rochelle, France, SBMI 2015 featured nine accepted papers and an invited presentation, titled “Motion Detection: Unsolved Issues and [Potential] Solutions,” by Pierre-Marc Jodoin from the University of Sherbrooke, Canada.

Tremendous technological advances in the area of video compression and communication made image/video over the Internet and wireless mobile networks an inevitable part of our lives. Indeed, video traffic is exploding over the Internet, and is becoming a dominant application over 3G/4G mobile systems. The necessity for seamless access and exchange of a large amount of multimedia content anytime and anywhere by mobile users is driving intensive research within this field as it provides a number of business opportunities through commercial multimedia application provisioning. High user satisfaction with multimedia services is the most meaningful quality evaluation criterion. For this reason the set of issues encompassed by the term quality of experience (QoE), i.e., the quality perceived subjectively by the end-user, is key to service providers, network and software engineers, developers, and scientists. To address the ever-increasing consumer requirements, the emerging solutions for multimedia delivery over next-generation networks have to rely on the state of the art in multimedia processing and communications. The goal of the workshop on Image and Video Processing for Quality of Multimedia Experience — QoEM 2015, organized by Nicu Sebe - University of Trento, Italy, Ben Herbst - Stellenbosch University, South Africa, and Dubravko Culibrk - University of Trento, Italy / University of Novi Sad, Serbia — is to give an overview of the recent technologies and system solutions, as well as create a forum to exchange ideas and address challenges emerging in this field. The technical program featured oral presentations of all six accepted regular papers.

On the whole, the addressed topics constituted a good mix between current trends in computer vision and the fundamentals of image analysis and pattern recognition.

BioFor 2015 - International Workshop on Recent Advances in Digital Security: Biometrics and Forensics

Reflectance Normalization in Illumination-Based Image Manipulation Detection	3
<i>Christian Riess, Sven Pfaller, and Elli Angelopoulou</i>	
Evaluation of Residual-Based Local Features for Camera Model Identification	11
<i>Francesco Marra, Giovanni Poggi, Carlo Sansone, and Luisa Verdoliva</i>	
Biometric Walk Recognizer	19
<i>Maria De Marsico and Alessio Mecca</i>	
Touchstroke: Smartphone User Authentication Based on Touch-Typing Biometrics	27
<i>Attaullah Buriro, Bruno Crispo, Filippo Del Frari, and Konrad Wrona</i>	
EEG/ECG Signal Fusion Aimed at Biometric Recognition	35
<i>Silvio Barra, Andrea Casanova, Matteo Fraschini, and Michele Nappi</i>	
Fusion of Holistic and Part Based Features for Gender Classification in the Wild.	43
<i>Modesto Castrillón-Santana, Javier Lorenzo-Navarro, and Enrique Ramón-Balmaseda</i>	
A Hand Gesture Approach to Biometrics	51
<i>Nahumi Nugrahaningsih, Marco Porta, and Giuseppe Scarpello</i>	
<i>Quis-Campi</i> : Extending in the Wild Biometric Recognition to Surveillance Environments	59
<i>João C. Neves, Gil Santos, Sílvio Filipe, Emanuel Grancho, Silvio Barra, Fabio Narducci, and Hugo Proença</i>	

CTMR 2015 - Color in Texture and Material Recognition

On Comparing Colour Spaces From a Performance Perspective: Application to Automated Classification of Polished Natural Stones	71
<i>Francesco Bianconi, Raquel Bello, Antonio Fernández, and Elena González</i>	

Methods for Predicting Spectral Response of Fibers Blends	79
<i>Rocco Furferi, Lapo Governi, and Yary Volpe</i>	
Texture Classification Using Rotation Invariant LBP Based on Digital Polygons	87
<i>Juan Pardo-Balado, Antonio Fernández, and Francesco Bianconi</i>	
Analysis of Albedo Influence on Surface Urban Heat Island by Spaceborne Detection and Airborne Thermography	95
<i>Giorgio Baldinelli and Stefania Bonafoni</i>	
An Interactive Tool for Speed up the Analysis of UV Images of Stradivari Violins	103
<i>Piercarlo Dondi, Luca Lombardi, Marco Malagodi, Maurizio Licchelli, Tommaso Rovetta, and Claudia Invernizzi</i>	
Local Angular Patterns for Color Texture Classification	111
<i>Claudio Cusano, Paolo Napoletano, and Raimondo Schettini</i>	
Complexity Perception of Texture Images	119
<i>Gianluigi Ciocca, Silvia Corchs, and Francesca Gasparini</i>	
RHEUMA 2015 – Medical Imaging in Rheumatology: Advanced Applications for the Analysis of Inflammation and Damage in the Rheumatoid Joint	
An MRI Study of Bone Erosions Healing in the Wrist and Metacarpophalangeal Joints of Patients with Rheumatoid Arthritis	129
<i>Francesca Barbieri, Veronica Tomatis, Giuseppe Zampogna, Elena Aleo, Valentina Prono, Stefania Migone, Patrizia Parascandolo, Lorenzo Cesario, Gianni Viano, and Marco Amedeo Cimmino</i>	
RheumaSCORE: A CAD System for Rheumatoid Arthritis Diagnosis and Follow-Up	135
<i>Patrizia Parascandolo, Lorenzo Cesario, Loris Vosilla, and Gianni Viano</i>	
A Database of Segmented MRI Images of the Wrist and the Hand in Patients with Rheumatic Diseases	143
<i>Veronica Tomatis, Marco Amedeo Cimmino, Francesca Barbieri, Giulia Troglio, Patrizia Parascandolo, Lorenzo Cesario, Gianni Viano, Loris Vosilla, Marios Pitikakis, Andrea Schiappacasse, Michela Moraldo, and Matteo Santoro</i>	

Novel Automatic Tool for Magnetic Resonance Imaging Quantification of Bone Erosion Scoring in Rheumatoid Arthritis 151
Patrizia Parascandolo, Lorenzo Cesario, Loris Vosilla, Francesca Barbieri, Marco Amedeo Cimmino, and Gianni Viano

Optimizing and Evaluating a Graph-Based Segmentation of MRI Wrist Bones 159
Sonia Nardotto, Roberta Ferretti, Laura Gemme, and Silvana Dellepiane

Generation of 3D Canonical Anatomical Models: An Experience on Carpal Bones 167
Imon Banerjee, Hamid Laga, Giuseppe Patanè, Sebastian Kurtek, Anuj Srivastava, and Michela Spagnuolo

ISCA 2015 - Image-Based Smart City Application

DicomPrint, an Application for Managing DICOM Images. 177
Edlira Kalemi, Edlira Martiri, Brunela Manaj, and Dionis Prifti

Accurate Positioning and Orientation Estimation in Urban Environment Based on 3D Models. 185
Giorgio Ghinamo, Cecilia Corbi, Piero Lovisolo, Andrea Lingua, Irene Aicardi, and Nives Grasso

An Hippocampal Segmentation Tool Within an Open Cloud Infrastructure. . . 193
Nicola Amoroso, Sabina Tangaro, Rosangela Errico, Elena Garuccio, Anna Monda, Francesco Sensi, Andrea Tateo, and Roberto Bellotti

A Survey on Traffic Light Detection 201
Moises Diaz, Pietro Cerri, Giuseppe Pirlo, Miguel Angel Ferrer, and Donato Impedovo

Saliency-Based Keypoint Reduction for Augmented-Reality Applications in Smart Cities 209
Simone Buoncompagni, Dario Maio, Davide Maltoni, and Serena Papi

A Likelihood-Based Background Model for Real Time Processing of Color Filter Array Videos 218
Vito Renó, Roberto Marani, Nicola Mosca, Massimiliano Nitti, Tiziana D’Orazio, and Ettore Stella

Smart Maintenance to Support Digital Life. 226
Federico Bergenti, Massimo Chiappone, and Danilo Gotta

FSSGR: Feature Selection System to Dynamic Gesture Recognition	234
<i>Diego G.S. Santos, Rodrigo C. Neto, Bruno Fernandes, and Byron Bezerra</i>	
Interoperability of Biometric Systems: Analysis of Geometric Characteristics of Handwritten Signatures.	242
<i>Giuseppe Pirlo, Fabrizio Rizzi, Annalisa Vacca, and Donato Impedovo</i>	
Computer Aided Evaluation (CAE) of Morphologic Changes in Pigmented Skin Lesions.	250
<i>Maria Rizzi, Matteo D'Aloia, and Gianpaolo Cice</i>	
Analytical Method and Research of Uyghur Language Chunks Based on Digital Forensics	258
<i>Yasen Aizezi, Anwar Jamal, Dilxat Mamat, Ruxianguli Abdurexit, and Kurban Ubul</i>	
CLICK TEATRO Project: Augmented Reality and Promotion of Theater Events	267
<i>Donato Barbuzzi, Bachir Boussahel, Francesca De Carlo, Angelo Galiano, Donato Impedovo, and Annalisa Longo</i>	
A Marker-Based Image Processing Method for Detecting Available Parking Slots from UAVs	275
<i>Matteo D'Aloia, Maria Rizzi, Ruggero Russo, Marianna Notarnicola, and Leonardo Pellicani</i>	
Crosswalk Recognition Through Point-Cloud Processing and Deep-Learning Suited to a Wearable Mobility Aid for the Visually Impaired. . .	282
<i>Matteo Poggi, Luca Nanni, and Stefano Mattoccia</i>	
Early Diagnosis of Neurodegenerative Diseases by Handwritten Signature Analysis.	290
<i>Giuseppe Pirlo, Moises Diaz, Miguel Angel Ferrer, Donato Impedovo, Fabrizio Occhionero, and Urbano Zurlo</i>	
A New Context-Aware Computing Method for Urban Safety	298
<i>Hyeon-Woo Kang and Hang-Bong Kang</i>	
MADiMa 2015 - First International Workshop on Multimedia Assisted Dietary Management	
Estimating the Nutrient Content of Commercial Foods from their Label Using Numerical Optimization	309
<i>Jieun Kim and Mireille Boutin</i>	
The Use of Temporal Information in Food Image Analysis	317
<i>Yu Wang, Ye He, Fengqing Zhu, Carol Boushey, and Edward Delp</i>	

Tastes and Textures Estimation of Foods Based on the Analysis of Its Ingredients List and Image 326
Hiroki Matsunaga, Keisuke Doman, Takatsugu Hirayama, Ichiro Ide, Daisuke Deguchi, and Hiroshi Murase

Food Recognition and Leftover Estimation for Daily Diet Monitoring 334
Gianluigi Ciocca, Paolo Napoletano, and Raimondo Schettini

Mobile Computing and Artificial Intelligence for Diet Management. 342
Alessandro Mazzei, Luca Anselma, Franco De Michieli, Andrea Bolioli, Matteo Casu, Jelle Gerbrandy, and Ivan Lunardi

Highly Accurate Food/Non-Food Image Classification Based on a Deep Convolutional Neural Network 350
Hokuto Kagaya and Kiyoharu Aizawa

A Printer Indexing System for Color Calibration with Applications in Dietary Assessment 358
Shaobo Fang, Chang Liu, Fengqing Zhu, Carol Boushey, and Edward Delp

Food Object Recognition Using a Mobile Device: State of the Art 366
Simon Knez and Luka Šajn

On the Exploitation of One Class Classification to Distinguish Food Vs Non-Food Images. 375
Giovanni Maria Farinella, Dario Allegra, Filippo Stanco, and Sebastiano Battiato

Food Recognition Using Consensus Vocabularies 384
Giovanni Maria Farinella, Marco Moltisanti, and Sebastiano Battiato

Using Small Checkerboards as Size Reference: A Model-Based Approach . . . 393
Hamid Hassannejad, Guido Matrella, Monica Mordonini, and Stefano Cagnoni

Fractal Nature of Chewing Sounds 401
Vasileios Papapanagiotou, Christos Diou, Zhou Lingchuan, Janet van den Boer, Monica Mars, and Anastasios Delopoulos

Objective and Subjective Meal Registration via a Smartphone Application . . . 409
Ioannis Moulos, Christos Maramis, Ioannis Ioakimidis, Janet van den Boer, Jenny Nolstam, Monica Mars, Cecilia Bergh, and Nicos Maglaveras

Towards an Engaging Mobile Food Record for Teenagers	417

demarsico@di.uniroma1.it, alessio.mecca@hotmail.com

Abstract. In this paper we present a comparative test of different approaches to gait recognition by smartphone accelerometer. Our work provides a twofold contribution. The first one is related to the use of low-cost, built-in sensors that nowadays equip most mobile devices. The second one is related to the use of our system in identification mode. Instead of being used to just verify the identity of the device owner, it can also be used for identification among a set of enrolled subjects. Whether the identification is carried out remotely or even if its results are transmitted to a server, the system can also be exploited in a multi-biometric setting. Its results can be fused with those from computer-vision based gait recognition, as well as other biometric modalities, to enforce identification for accessing critical locations/services. We obtained the best results by matching complete walk captures (Recognition Rate 0.95), but the implicit limitation is represented by the fixed number of steps in the walks. Therefore we also investigated methods based on first dividing the signal into steps. The best of these achieved a Recognition Rate of 0.88.

Keywords: Biometrics · Gait recognition · Accelerometer · Mobile devices

1 Introduction

Biometric recognition is attracting increasing interest, since in many environments it can provide efficient means of identity recognition. Some biometric traits can be considered as *strong*, since they allow robust authentication especially in controlled settings. Examples are face, iris, and fingerprints. Strong biometrics often concern physical traits. Other traits, mostly *behavioral* ones, can be less reliable, for example because they can be affected by emotional conditions. At present, gait recognition, i.e. recognizing people from the way they walk, is often classified in the latter category. It can be used to complement other strong or soft traits in a multi-biometric approach, and is one of the recent attractive topics in biometric research. Gait recognition modalities can be categorized into three groups based on the technological setting they require: a) machine vision-based: these approaches suffer from typical image processing issues, e.g., occlusions and illumination variations; b) floor sensor-based: these approaches require specific ambient equipment, therefore cannot be used everywhere and require a preliminary complex set-up; c) wearable sensor-based: these approaches can be further distinguished according to the number and kind of sensors exploited (more accelerometers, accelerometers plus gyroscopes, etc.).

Given the limitations of the first two groups of techniques in terms of feasibility and ready availability, we will focus on the third group. Even in this case, we aim at exploiting the simplest possible set-up. It is easy to assume that such set-up should use off-the-shelf, widespread equipment, and possibly exploit only one sensor of one kind, to keep the method feasible on a wide range of devices. Moreover, it would be desirable to exploit the least computationally demanding procedure.

We present the results obtained using the accelerometer built in the OnePlus One mobile phone, and compare different matching algorithms to evaluate the better compromise between accuracy and computational cost. The latter would allow performing recognition both locally, e.g., on a smartphone, or remotely on a computer receiving gait data. Moreover, we will test these techniques in identification modality (no identity is claimed by the user). This also allows combination with other biometrics to secure the access not only to personal devices but also to locations or services. On the contrary, most approaches in literature use (implicit) verification: the identity claim is implicit in the preliminary enrollment of a single user, namely the owner of the device, and the algorithms aim at verifying if the user keeping the device is the owner. In identification, assuming open set mode (probe user may not be known to the system), a template distance threshold regulates acceptance as in verification; in addition the right subject has not only to be close enough, but also to be the closest one.

2 State of the Art for Accelerometer-Based Gait Recognition

During the last years, among the approaches mentioned above, the gait recognition based on wearable sensors is becoming increasingly popular in respect to the others. This is because, on one hand, the related techniques used for recognition are less computationally expensive, and wearable sensors have a cost much lower than cameras and floor sensors; on the other hand achieved results are similar or even better. Wearable sensors do not suffer from the problems normally raised by computer vision-related techniques, e.g., occlusion, and illumination. In addition, differently from approaches based on floor sensors, the subject can be followed in any place without the need to equipping the environment. Last but not least, nowadays the most common wearable sensor used for gait recognition, the accelerometer, is practically built in most portable devices such as mobile phones and tablets. This avoids the use of expensive ad-hoc equipment. The reader can find in [1] a comprehensive survey on present approaches to gait recognition divided into the three mentioned main groups; [2] provides a review of present vision-based technique, the most used so far.

In most papers about gait recognition by accelerometer, the aim is to identify the owner of the phone. The recognition modality is verification: the identity claim is implicit, since only the owner is enrolled. Performances are usually measured by computing all-against-all matching results in a set of subjects. For verification, the performance measures are False Acceptance Rate (FAR), False Reject Rate (FRR) and Equal Error Rate (EER) given by the acceptance threshold were $FAR=FRR$.

In [3] the authors use the low sampling rate accelerometer that is built-in in Google G1 phone. Their system achieves an EER of 20% with a dataset of 51 volunteers. The algorithm uses cycle detection, computes average cycle and uses Dynamic Time

Warping for matching. The EER is not that low, however this is also due to the very low quality of the used accelerometer. As a matter of fact, in [4] a pair of the same authors improve their previous results using a better accelerometer, Motion Recording 100, which is not built in a mobile personal device. They perform some preprocessing operations, such as outlier steps removal, before matching performed by Dynamic Time Warping (DTW). The dataset size is increased to 60 users and the achieved EER is 5.7%. In comparison with this approach, we compute the average cycle to discard outliers, but we do not use it for matching. In addition, we also test our system in identification mode, which in some cases might be more challenging. While verification just requires sufficient similarity with the claimed identity, in identification one also has to avoid confusion between candidate identities, i.e., the right subject must not only be close enough, but also be the closest one. For both verification and identification the degree of similarity must be very high to obtain a correct answer of the system. However, consider a person that in identification modality is close enough but is not the closest one to the right one, and hence is not erroneously identified, e.g., as the owner of the device. This person, in verification modality, could be erroneously interpreted as the owner of the device if the similarity is just sufficiently good.

The recognition technique presented in [5] uses an accelerometer which is a standard in nowadays mobile devices, with sampling rate of 100 samples/second. They achieve a 5% of EER using histogram similarity and a 9% of EER using cycle group matching. However, though using the same accelerometer as in the preceding work, they use a smaller dataset (21 users). They do not report results for identification.

The work in [6] presents a framework for gait recognition using an Android mobile phone to get the accelerometer and gyroscope raw data. Verification is carried out on a desktop computer to recognize if the person who is walking with the phone is the enrolled user. The framework uses continuous wavelet transform time frequency spectrogram analysis for feature extraction and cyclostationarity analysis for matching. The tests achieve a 99.4% of verification rate at 0.1% of FAR for pace walk VS pace walk, 96.8% for fast walk VS fast walk, and a 61.1% for pace walk VS fast walk on a dataset of 36 users. This work achieves good results but uses the gyroscope too. In [7] the authors use Hidden Markov Model (HMM). They achieve a 10.42% of False Non Match Rate and a 10.29% of False Match Rate on a dataset of 48 users. The system uses only one enrolled user for training the HMM. All the registrations for all users are used as probe to test performance of verification. The performances achieved by this method are not competitive with the above ones.

The work in [8] exploits a signature point based method for identification. The user is recognized among a set of enrolled subjects. The system exploits five accelerometers attached in various parts of the body. This method does not use the cycle division as the others discussed above. It achieves a high recognition rate (96.7%) with a dataset of 30 users. In [9] an evolution of the previous method is proposed, and is used for both identification and verification modalities. It uses clustering to preliminarily group the signature points. The authors have also created a huge dataset (with 175 different subjects) of raw acceleration data, which is publicly available for

non-commercial use¹. On this dataset they achieve a Recognition Rate (RR) of 95.7% for identification and a 2.2% of EER for verification. This method achieves the best results among the mentioned ones, but uses a very complex equipment.

3 The Approaches We Tested

We now describe the different approaches we tested, starting from the best performing yet more constrained one, and releasing constraints afterwards. As for most papers in Section 2, the matching algorithm exploits DTW (in its basic version).

In order to capture the gait information, we chose 3-axis accelerometer as other related works. This sensor seems to better monitor the exact movement of a subject in the space, and nowadays is widespread and simple to set up, being built in most normal Android phones. The components exploited by our system are a OnePlus smartphone equipped with a 3-axis accelerometer and a desktop computer with Java Virtual Machine. We have not addressed interoperability issues yet, therefore the devices for enrollment and testing need to be of the same model.

Among the apps for monitoring and recording the accelerometer data, we chose Physics Toolbox Accelerometer, available on Google Play². This application has a number of advantages among which the instant saving of data in Comma Separated Values (CSV) format. Moreover, the app is light, very fast, and compatible with any device with an accelerometer, including less recent versions of Android or less performing devices. Android captures accelerometer information automatically in an intelligent way: once the designer has set a minimum threshold of time to acquire the information, the data capture along the three axes is done according to a sampling density that depends on the displacement of the device relative to the previous position, i.e., the lower the variation the sparser the sampling and vice versa. Many approaches include time interpolation to obtain fixed intervals, but we avoid this step.

3.1 Enrollment Phase

In enrollment phase, our goal is to obtain a uniform enough data capture, which is quite usual in most applications. Therefore we decided to standardize the movements for each recording according to the following procedure: 1) the subject is asked to put the phone in the belt, either on the right hip or on the left one, in vertical position with the screen facing out (because recording is ended by tapping on the screen), in about the same position for all users; 2) the subject is then asked to keep feet together and start walking by the leg opposite to phone location; 3) the system records 10 steps along a straight line in the most natural way. For each enrolled user a folder is created on the desktop computer, where data is transferred (manually by now), and results of possible processing are stored. At the moment, we acquire data for three different user walks that during tests are used from time to time as probe or as gallery (during identification, probe data

¹ <http://www.ytzhang.net/datasets/zju-gaitacc>

² <https://play.google.com/store/apps/details?id=com.chrystianvieyra.android.physicstoolboxaccelerometer&hl=it>

is matched with data from two different instances of walk). However, all approaches can handle a different number of templates per enrolled user. At present the dataset has 26 users, wearing different shoes (but no high heels).

In order to have each walk signal starting from a relevant point, we discard all initial local maxima created by noise. To do this, we use a threshold experimentally set at 1.05 on y axis (this value is device dependent). After the procedure finds the first value greater than the threshold, the system searches for the first relative maximum from that point. Once this has been identified, it is saved and will be the starting point of the vector that will be used by matching. A similar procedure is used to identify the useful end of the signal. As for now, the same threshold is used.

The system uses the DTW separately for each axis. In order to investigate an effective fusion of the three results for each comparison into a final similarity, we preliminarily studied the plots returned and performed some tests. In most cases, and considering that axes depend from the device position, our y-axis is the most important for recognition, followed by z-axis. The resulting weights are very similar to those used in other works in literature. The x-axis of our device has very little impact on the recognition. All walks achieve a very similar value on that axis, mainly because it assumes specific meanings only in case of strong jerks or jumps, that are generally absent in natural walking. We perform a linear combination of the three values using experimentally determined weights that depend on the processing method (see below).

3.2 Testing Phase and Experimental Results

As for testing, we investigated different possibilities, that we will denote according to the way walk data is pre-processed and to the way matching is performed: Walk, Best Step and Best Step VS All, AllSteps VS All, and Steps Sliding Window. The pre-processing described above applies to all. We apply essentially two strategies. The first one exploits the overall signal for matching, and is implemented only in the Walk method. All the others rely on a preliminary segmentation of the walk signal into steps, and on the possible discarding of outliers. This further pre-processing phase is applied to both gallery templates and to the probe. We first identify the starting and ending points of the useful portion of the signal using the thresholds mentioned above. Afterwards, for each walk belonging to the same user, maxima are extracted and ordered by amplitude. We underline that, thanks to the way we ask the user to walk, we can assume a certain distribution of maxima within the signal. In particular, each step is generally characterized by a first higher peak, corresponding to moving the leg with the accelerometer, and a second higher peak corresponding to moving the other leg. Moreover, it contains many further local maxima corresponding to noise. For each walk in the gallery, local maxima are extracted and ordered. In doing this, we consider the *#walks* sequences captured for a user all together. The value of the local maximum in position $10 * \#walks$ of this ordered list is taken as the threshold for step segmentation for the user at hand. Maxima higher than such threshold are taken as the starting points of new steps. In this way, we obtain on average 10 steps per walk for each user, unless some error happens. Moreover, we discard outliers. After dividing the walk into steps, we use DTW to compute pairwise differences and discard steps showing a distance from the others higher than the average distance plus

the variance. In our case, we have an average of 20 steps per registered user. For each user, the threshold identified for step segmentation is stored together with the whole walk as well as the identified steps, with and without the outliers. At present, we assume closed set identification (the user is in the database) but setting a threshold is sufficient to pass to open set identification (the user might be unknown).

Walk. In Walk method, it is assumed that the probe contains the same number of steps as the gallery templates. The probe walk is matched against all stored walks (at present, two for each enrolled user). The system returns the labels of the candidates ordered by decreasing distance of each walk from the probe (the two walks for the same user are not necessarily close in the returned list). We use the following weights to combine results from the axes: $x\text{-axis}=0$, $y\text{-axis}=0.8$, $z\text{-axis}=0.2$.

Notwithstanding the simple approach, Walk modality achieves very interesting identification results. Notice that Recognition Rate (RR) is above 0.95 in the best test. However, the limitations given by the strictly controlled acquisition, especially the fixed number of steps, make this method not much appealing for real-world settings.

Best Step and Best Step VS All. These methods are a first attempt to overcome the limitations of Walk. They use step segmentation and outlier elimination, also for the probe. A further information is stored during the enrolling phase: the centroid of steps for each enrolled user is computed using DTW-based distances, and is saved in the gallery. It should represent the *average* user's step. During testing by Best Step, this *centroid step* of each user in the gallery is matched against the *centroid step* of the probe. For each matching operation, the probe is segmented into steps using the segmentation threshold stored in the gallery for the user to match. This algorithm achieves much lower performances with respect to Walk, with a RR of only 38.5%. It is reasonable to assume that this is due to the reduced size of the matched signal (a single step) which is the only information used to determine the final distance. We also tried to match the centroid step of each enrolled user to all steps of the probe, to take the minimum distance as result (Best Step VS All). However, this achieved the worst result of all algorithms we tried (a very poor RR of 23.1% in the best test).

AllSteps VS All. In AllSteps VS All method (AllSteps for short), we perform segmentation as described above and discard outliers, also for the probe. The identification phase is more articulated in this modality. For each gallery user, we divide the probe walk according to the user-specific threshold. For each step so obtained, we compute the minimum distance from the steps of that user. The final distance will be the average of all probe step minimum distances. The linear combination of results from the three axes is performed using the following weights: $x\text{-axis}=0.1$, $y\text{-axis}=0.7$, $z\text{-axis}=0.2$ (yet with very little performance decrease with the same Walk weights).

The reverse of the medal for all methods allowing much more freedom in the probe walk, i.e., that avoid setting in advance any number of steps in testing operations, is a decrease in performance, which is lower for this one, i.e., a RR of above 0.88 is achieved in the best test that corresponds in any case to a very promising result.

Steps Sliding Window. This method tries to recover some of the accuracy achieved by Walk. It uses segmentation just to compute the number of steps in the signal to

match, and of course does not discard outliers, since matching is performed on sequential portions of the signals. We consider a window of x steps, where x is the minimum between the total number of steps of the probe and the total number of steps for the enrolled user being matched. The method applies DTW by sliding the shortest window over the longest one, and returning the minimum distance found. The weights assigned to axes are: x-axis= 0, y-axis=0.6, z-axis=0.4. This is the computationally most expensive among the tested algorithms and achieves a RR of 84.6% in the best test. In fact, it is slightly worse than AllSteps and also more onerous.

Figure 1 summarizes the achieved results in terms of Cumulative Match Curves (CMCs) in the best test. Since Walk returns ordered walks, while the others return ordered identities, the plot for Walk spans more ranks. We also performed a kind of 3-fold validation, with each gallery template playing in turn the role of probe. To stress the Walk experimental setting, we did not repeat it three times with a balanced number of templates between the identity corresponding to the probe and those of the others: in each experiment we picked one template per user as probe (so that only two were left in the gallery) and matched it against all three templates of the other users. Results were only slightly worse, with similar relative performance of methods.

We tested the system for verification too using an all-against-all procedure. We assigned to each probe the identity of all enrolled users in turn (claim). Impostors were obviously much more than genuine users ($l_{\text{probel}} * l_{\text{gallery}} - 1$ impostors and l_{probel} genuines). The results confirm the relative performance for the different methods. We achieved the following ERR values: 7.69% for Walk, 30.46% for Best Step, 30.92% for Best Step VS All, 10.46% for AllSteps, and 15.38% for StepSlidingWindow. This confirms that the use of the centroid step is the worst strategy for verification too. Walk confirms to be the best method while the two methods with less restriction, i.e., AllSteps and StepSlidingWindow, achieve an acceptable result.

3.3 Discussion and Conclusions

This work presented a preliminary investigation on biometric identification by gait recognition via smartphone accelerometer. We tested different methods, starting from Walk that requires a fixed number of steps, but achieved the best results (RR above 0.95, EER 7.69%). The best compromise between low constraints and good accuracy is AllSteps (RR above 0.88, EER 10.46%). Identification results are confirmed in a kind of 3-fold validation. Methods achieving better results for verification used a more complex equipment and/or more expensive computational methods.

The only method in related work achieving better results in identification modality (RR 95.5% with no limitation on walk length) uses 5 accelerometers, therefore it is not suited for use with personal mobile devices. Moreover, the reported results using only the accelerometer located on pelvis, which is the same setting as our, only reach an RR of 73.4%, yet with a larger gallery. We will test further modalities and future work will address a number of issues. We will study how to make the method interoperable, by devising a kind of signal normalization procedure allowing to match signals from different accelerometers. We will also extend the database in less controlled or adverse conditions, i.e., by shoes with heels, and at different walking pace.
